

THE CHOICE OF OPERATIONS IN THE TREATMENT OF PEPIC ULCER

GEORGE J. HEUER, M.D.

New York City

It requires a good deal of assurance to state the choice of operations in the treatment of peptic ulcer when there seems to be, even at the present time, so much difference of opinion regarding the matter. Like all of those doing research in this line, I have been seeking the ideal method of treatment and have not found it, but in the course of my search I have gathered impressions which undoubtedly have shaped my present attitude toward the treatment of this disease. These impressions I shall not relate but I frankly may say that they have resulted in an attitude toward the surgical treatment of peptic ulcer which may be called conservative. I have critically examined them in the light of my own experience and the experiences of others as gathered from the literature, and I shall present the conclusions I have reached.

Not the least difficult part of the whole subject is the attempt to appraise the many conflicting results which occur in the literature. The highly satisfactory results of one observer with a given method when contrasted with the far less satisfactory results of another with the same method leads to the thought that the judgment, mechanical sense, and technical skill of the surgeon, the differing criteria in judging results and constitutional and environmental factors all play a rôle in determining the value of a given surgical operation. It is a question whether to judge the merits of a surgical procedure by the best or by the poorest results obtained by its use. In my judgment it is better to judge it by the former than by the latter, and for obvious reasons.

The reader is no doubt familiar with the development of the surgical treatment of peptic ulcer. Merren, of Giesen, in 1810

first resected the pylorus in dogs, Plan, in 1879, first resected the stomach of man for gastric ulcer; Wolfier, in 1881, first performed a gastro-enterostomy for pyloric cancer; and Doyen, in 1898, first performed a gastro-enterostomy for duodenal ulcer. Since these earlier efforts surgeons have devised a large number of operative methods for the treatment of gastric and duodenal ulcer. These I do not intend to enumerate or describe in detail for they are well known. Evolved in general upon the two principles of excision of the offending lesion or of curative rest through diversion of the alimentary stream, each has had its advocates, each has won a following, none has yielded perfectly satisfactory results. Some, as gastro-enterostomy, have in spite of the newer procedures continued in use and successfully stood the test of experience; others have had periods of enthusiastic support which they have been unable to maintain. As surgeons have determined the value of these various procedures by the important test of late results, it is becoming clearer what we may reasonably expect from them from the standpoints of mortality and of late results. I shall examine the mortality and late results not of all the procedures devised but of those which may be, and have been, used in the treatment of the vast majority of ulcers. This would appear to be one of the steps toward the decision of the choice of operations for peptic ulcer. For the sake of convenience, I shall assemble the results for duodenal and gastric ulcer separately.

DUODENAL ULCER

It would appear from the accumulated experience now available in the literature with which our own experience coincides

that in the treatment of duodenal ulcer only 3 methods of attack or 3 varieties of operative procedure need be considered. These are (1) local excision of the ulcer combined with some form of pyloroplasty, (2) simple gastro-enterostomy, and (3) pylorectomy or partial gastric resection.

1. **EXCISION AND PYLOROPLASTY.**—By this I refer to an operative procedure exemplified by the operation of E. Starr Judd and that of J. M. T. Finney. In the operation of Judd the ulcer, preferably one on the anterior or ventral duodenal wall, is excised with an incision which extends through the pylorus, stomach and duodenal wall. To the excision of the ulcer is added the resection of a large part of the pyloric sphincter. The purpose of the operation is then two-fold: to remove the lesion and to prevent subsequent pylorospasm. The operation of Finney (Finney pyloroplasty) is well known and need not be described. Its important features are that it permits the excision of ulcers of the anterior and sometimes of the posterior wall; it greatly enlarges the pyloric opening, and it prevents pylorospasm by division of the sphincter. Both the operations of Judd and Finney have then the important purposes of excision of the ulcer and the prevention of subsequent spasm of the pyloric sphincter.

Results.—Judd¹ reports 1,363 cases of duodenal ulcer operated upon by this method, with a mortality of 0.4 per cent. The late results in 464 cases treated between 1924 and 1928 by excision and pyloroplasty show a satisfactory result in 90 per cent of the cases, an unsatisfactory result in 8.1 per cent of the cases.

Finney² reports 149 cases treated by his method of pyloroplasty with a mortality of 2.7 per cent. The late results show a satisfactory outcome in 86.8 per cent, an unsatisfactory result in 13.2 per cent.

From the more recent literature I have assembled the results of similar local operations or pyloroplasties in the treatment of duodenal ulcer. In 192 cases assembled the general mortality is higher than in Judd's and Finney's cases and the late satisfactory results do not average much above 60 per cent. The total is made up of scattered reports of small numbers of cases and by surgeons who evidently have not included the operation among their favorites. The results, therefore, are less likely to represent the possibilities in the methods than

those which have been obtained by surgeons who have perfected it.

2. **GASTRO-ENTEROSTOMY.**—This indirect attack upon duodenal ulcer requires no description; nor shall I discuss the relative merits of the varieties of gastro-enterostomy as anterior and posterior, long-loop and short-loop, antiperistaltic and isoperistaltic; except to say that in my opinion the posterior short or no-loop gastro-enterostomy gives the best results.

Results.—Balfour³ in a carefully studied series of 500 cases of duodenal ulcer in which gastro-enterostomy alone was done finds a mortality of 1.8 per cent. The late results after a minimum of 5 years after operation shows a satisfactory outcome in 87 per cent and an unsatisfactory outcome in 13 per cent. The follow-up studies show that the operation protects the patient against perforation of the ulcer and protects, although to a lesser extent, against hemorrhage from the ulcer. Nine per cent of the cases had one or more hemorrhages after operation but only one of the 500 patients died from hemorrhage. Recurrent ulceration after the operation occurred in 4 per cent of the cases. Gastrojejunal ulcer (marginal ulcer) occurred in 3.2 per cent in a period of ten years after operation. Space limitations do not permit the citation of the results of a large number of distinguished surgeons who have been interested in this field. I have collected 1,599 gastro-enterostomies for duodenal ulcer from the recent literature with a general mortality of 6.8 per cent, an individual mortality which varies from 2.1 to 10 per cent. The general late results show that in 85 to 92 per cent satisfactory relief from symptoms has been obtained in American clinics, from 65 to 75 per cent in German clinics. Gastrojejunal ulcer has been a late complication of the operation in from 1.6 to 7 per cent in the experience of various surgeons. In addition to these I have collected 1,490 cases of peptic ulcer treated by gastro-enterostomy in which the distinction between duodenal and gastric ulcer is not made. The results may be expected to be less satisfactory than those for duodenal ulcer alone. Nevertheless, they show a mortality which varied generally between 2.7 and 7.7 per cent, but in two instances are 10 and 15 per cent. Satisfactory results were obtained in 80 per cent of the cases. Gastrojejunal ulcer occurred with about the same frequency as duodenal.

3. PYLORECTOMY OR GASTRIC RESECTION.—This more radical procedure for the treatment of duodenal ulcer has been employed in the hope of improving the results obtained by the simpler methods. The operation has been used less frequently in this country than in European clinics. I have collected 865 cases of duodenal ulcer from the recent literature, in which gastric resection was performed by the methods of Billroth I and II and of Polya or its modifications. The general mortality is around 12 per cent; the individual mortality varies from 0 to 25 per cent. The late results show satisfactory relief from symptoms in 80 to 85 per cent of cases. Operations as the Billroth II failed to prevent subsequent development of gastrojejunal ulcer, although the incidence of this complication seems to be lower than after gastro-enterostomy.

While I have assembled the results in only 3 procedures in the treatment of duodenal ulcer and have stated that they have been used in the great majority of cases of duodenal ulcer, it is self-evident that in certain cases combinations of procedures, such as local excision and gastro-enterostomy, may seem the operation of choice. While I have no statistics to support the statement I doubt whether the regular use of these combinations has improved the results of the individual procedures. The results of the Devine operation, I have not been able to estimate. Its use is limited to a special group of cases.

CHART 1.—DUODENAL ULCER

Author	No. of Cases	Mortality, per cent	Good results per cent	Jejunal ulcer, per cent
<i>Treated by pyloroplasty</i>				
Judd	1,363	0.4	90

GASTRIC ULCER

There has been a general agreement that the surgical results in the treatment of gastric ulcer are less satisfactory than in duodenal ulcer. This and the known greater tendency of gastric ulcer to undergo malignant change has led surgeons to adopt a more radical attitude toward ulcer of the stomach. While the trend in general in the treatment of duodenal ulcer has been toward conservative operations, the trend of late years in gastric ulcer has been toward resection of the stomach. In the treatment of gastric ulcer four methods of procedure need be considered, excision and pyloroplasty, gastro-enterostomy, excision and gastro-enterostomy, and gastric resection.

1. EXCISION AND PYLOROPLASTY.—This operation is applicable to lesions at or near the pylorus. It is difficult to obtain from the literature any but scattered reports of small numbers of specified gastric ulcers treated by this method. The series of Finney² is the largest I have found and because of his long-continued interest in this operation and his perfection in its technic probably represents the best results that may be expected from this method. In 102 cases of gastric ulcer the mortality was 8.8 per cent and satisfactory results were obtained in 83.9 per cent.

2. GASTRO-ENTEROSTOMY.—Gastro-enterostomy alone recently has probably been used most commonly in the ulcers near the pylorus and in those high upon the cardia in which resection of the stomach is inadvisable or impossible. In 641 gastric ulcers treated by gastro-enterostomy the general mortality in the larger series of cases is 8.9 per cent, the individual mortality varies between 3 and 13 per cent. Satisfactory late results were obtained in 71 per cent of these cases. Individual results varied between 50 and 82 per cent, with the majority of individual results over 75 per cent. As I noted in discussing duodenal ulcer, I have collected 1,490 cases of undifferentiated peptic (gastric and duodenal) ulcer treated by gastro-enterostomy with an average mortality of 4.8 per cent and with good results in 80 per cent. The more favorable mortality rate and the better late results in the latter group may be due to the duodenal ulcers included; but taken together these two groups of cases seem to show what results may be expected from gastro-enterostomy in gastric ulcer. Balfour³ has

made an interesting study of a selected group of 100 cases of gastric ulcer in which the lesion at operation was deemed irremovable and in which gastro-enterostomy alone was performed. The mortality following gastro-enterostomy was 3 per cent. The late results after a period of 5 years or more showed 79 per cent satisfactory results. The operation afforded almost complete protection against perforation and obstruction and a high protection against hemorrhage. Gastrojejunal ulcer did not occur in a single case. The development of carcinoma presumably in an unremoved lesion was established or suspected in 6 cases. The series shows what unexpectedly good results may be anticipated from gastro-enterostomy alone. While gastrojejunal ulcer did not occur in this series, it has occurred in the experience of others in perhaps 4 to 5 per cent of the cases.

3. GASTRIC RESECTION.—The operation is used for the lesions proximal to the pylorus by preference by some, by others in cases in which excision and pyloroplasty or excision and gastro-enterostomy seem inadvisable. It is used also in lesions further proximal upon the lesser curvature and fundus, the operation involving the removal of a large portion of the stomach. The types of operation commonly employed are the Billroth I, Billroth II, and Polya with its various modifications. It has been difficult to assemble the results separately of the lesser and greater gastric resections and I shall have to consider them together. The operations have had a greater vogue in Europe, particularly in Germany, than in this country, although a few surgeons here have taken them up enthusiastically. From the literature I have collected 430 cases of gastric ulcer treated by gastric resection. The general mortality is 12.4 per cent, the individual mortality varies from 5 to 30 per cent. The late results show satisfactory relief from symptoms in 73 per cent of the cases. The satisfactory results of individual surgeons vary between 55 and 88 per cent. The majority of surgeons have had over 78 per cent satisfactory results. In addition to these specifically designated gastric ulcers, I have assembled 5,243 undifferentiated peptic ulcers (presumably the majority gastric) from the literature. The very large majority are from the German literature. The general mortality following gastric resection is about 7 per cent—a mortality considerably lower than that of

the majority of American authors. The individual good results vary between 50 and 95 per cent, the average being 75 per cent. One-half the individual surgeons or clinics had results of 80 per cent or better, one-half of 75 per cent or less. Gastrojejunal ulcer following operation is rarely noted in German statistics, has occurred in approximately 3 per cent of the cases in this country.

A study of these results shows that in *duodenal ulcer* the conservative operations of excision and pyloroplasty and gastro-enterostomy achieve as good results as the more radical operation of gastric resection and do so with an appreciably lower mortality. Both types of operation protect the patient to a considerable degree against hemorrhage and perforation. The question of malignant degeneration of the ulcer does not enter. The operation of gastro-enterostomy has the disadvantage that it is followed in perhaps 5 per cent of the cases by gastrojejunal ulcer; but this complication follows gastric resection also in perhaps 3 per cent of the cases. The conservative operations leave the surgeon with some more radical treatment in reserve should a recurrent ulcer or gastrojejunal ulcer develop; the radical operations leave him and his patient in difficulties.

CHART II.—GASTRIC ULCER

Author	No. of Cases	Mortality, per cent	Good results, per cent	Jejunal ulcer, per cent
<i>Treated by pyloroplasty</i>				
Finney	102	8.8	83.9
<i>Treated by gastro-enterostomy</i>				
Balfour	100	3.0	79	0
Other authors	641	8.9	71	4 to 5
Total ..	741			
<i>Treated by gastric resection</i>				
American authors ..	196	12.4		
		12.4	78	3
European authors ..	234			
Total ..	430			
<i>Undifferentiated peptic ulcers treated by gastric resection</i>				
American authors ..	563	13.5		
			75 to 80	3
European authors ..	4,680	5.5		
Total ..	5,243			

In *gastric ulcer* also the more conservative procedures of excision and pyloroplasty, gastro-enterostomy, and excision and gastro-enterostomy show as good results as those obtained by large gastric resections.

The mortality following these conservative operations is appreciably lower in this country than that following the more radical operations. The German mortality for gastric resection is approximately that of the American mortality for the more conservative procedures. Even if the mortality is the same, the advantage would seem to be with the conservative operations, for they avoid the removal of a large portion of the stomach and better allow subsequent procedures should late recurrence or gastrojejunal ulcer develop.

From the standpoint purely of results a conservative attitude toward the surgical treatment of peptic ulcer would seem the part of wisdom. Other factors enter into the choice of operations for peptic ulcer which may be discussed under the following headings:

PATHOLOGY OF PEPTIC ULCER

Experience over a long period of years shows that the danger of malignant degeneration of duodenal ulcer is so slight as to be disregarded. In gastric ulcer the tendency to malignant change has long been recognized but the frequency of this change has not yet been accurately determined. From clinical observations (e.g., Balfour³) made upon patients, a gastric ulcer not removed at operation may become malignant in perhaps 5 per cent of the cases. In the German literature the percentage would seem to be less than this. From pathological studies carcinoma arises from gastric ulcer in from 5 to 10 per cent of the cases (Newcomb⁴). The number of gastric ulcers which may become carcinomatous is in the opinion of surgeons large enough to warrant the removal of all gastric ulcers if removal is not attended with too great risk, it is not large enough, in my opinion, to warrant the removal of an ulcer if the removal seriously jeopardizes the patient's life. There is no evidence that I know, that the removal by local excision is more dangerous to the individual from the standpoint of subsequent cancer than is the removal by wide gastric resection.

AGE FACTOR

Judd and others in this country have emphasized the factor of age in the treatment of gastric and duodenal ulcer. It has been observed that young individuals (under 35) do not have as good results following the simpler, more conservative

operations for peptic ulcer as do older individuals. Redwitz⁵ of Bonn, in an analysis of the late results of gastroenterostomy for peptic ulcer in 184 cases, finds that 68 were under 35 years of age, 116 were over 35 years of age. The satisfactory late results in patients under 35 are 51.4 per cent, in patients over 35, 74.5 per cent. Certain German opinion is that ulcer in the young should be treated radically, in the older, conservatively. Judd is of the opinion that ulcers in younger individuals should be excised when possible.

CHART III—PERFORATED PEPTIC ULCER

Author		No of cases	Mortality per cent	Cure results per cent
<i>Treated by simple closure</i>				
Johnston (1925)		210	35.7	75
Other authors (recent)		1,271	31.7	41

Total		195		

SOCIAL AND ECONOMIC FACTORS

The varying results obtained in the treatment of peptic ulcer may in part be due to constitutional, social, economic, and other factors. The ability or the desire to follow a proper postoperative regimen, the ability to prevent overwork, worry and strain, and to secure proper food are all matters which influence the results of surgical treatment. The surgeon may be influenced in his choice of operation after a proper evaluation of these factors.

These then are the considerations which, in my opinion, should determine the choice of operation in peptic ulcer. They have to do with the relief of symptoms with the lowest mortality and the greatest preservation of normal structures, the protection against complications and against recurrence of ulceration. With them in mind the choice of operations in peptic ulcer would be as follows:

DUODENAL ULCER

A For the ulcer appearing on the anterior duodenal wall in cases without

such adhesions about the pylorus and duodenum as may prevent proper delivery and exposure of the duodenum, the operation of excision and pyloroplasty by the method of Judd, or if one has mastered its details, by the method of Finney, is preferable. If adhesions or anatomical considerations make adequate delivery or exposure of the duodenum difficult, gastro-enterostomy is preferable.

B. For the ulcer of the anterior and posterior wall, if both are recognized before beginning the operation, gastro-enterostomy would seem preferable. If the posterior lesion is discovered only after the opening of the duodenum done for the excision of the ulcer of the anterior wall and can be excised, the operation becomes that of excision and pyloroplasty. If it cannot be excised, then the operation develops into excision of the ulcer of the anterior wall and gastro-enterostomy.

C. For the cicatricial-ulcer-producing pyloric obstruction, gastro-enterostomy is preferable.

These procedures will serve for the treatment of the very large proportion of duodenal ulcers. The occasional ulcer may demand pylorotomy or gastric resection. For the duodenal ulcer with repeated massive hemorrhages threatening life none of the operations above mentioned suffice, nor will the exclusion operation of Devine. These ulcers, fortunately rare, lie upon the posterior wall of the descending portion of the duodenum and have eroded one of the large branches of the pancreaticoduodenal artery. In one case of this sort during the past year a direct exposure of the ulcer by longitudinal incision of the duodenum showed an open artery in the base of the ulcer of such size that nothing short of an encircling ligature could control the hemorrhage. In a second case death from hemorrhage occurred soon after the patient's admission and before operation was undertaken. The autopsy showed an ulcer in the same location as in the previous case, in the base of which was a large open artery.

GASTRIC ULCER

A. For the ulcer at or near the pylorus in which the operations of Judd or Finney are possible, either of these operations would seem preferable.

B. For the ulcer too far proximal to the pylorus to permit excision and pyloroplasty, excision and gastro-enterostomy if fea-

sible, or pylorotomy by the methods of Billroth I or II and of Polya, if not feasible, would seem desirable. In certain cases under certain conditions simple gastro-enterostomy will be the operation of choice. These conditions have to do with the dangers to the patient of other procedures.

C. For the ulcer higher on the lesser curvature local excision and gastro-enterostomy is the operation of choice. The large gastric resections done for ulcer located in this region of the stomach seem unwarranted from the standpoint of results.

D. For the ulcer high upon the lesser curvature so near the esophageal opening that excision and gastro-enterostomy is impossible, simple gastro-enterostomy is the operation of choice.

These operations again will serve for the large majority of gastric ulcers. It is clear, as I stated in connection with duodenal ulcer, that the occasional ulcer will demand some other treatment than herein outlined.

In the treatment of peptic ulcer the operative method while of great importance, is of no greater importance than the experience, the skill, and the judgment of the surgeon. It is apparent that in the treatment of peptic ulcer the surgeon must approach each individual case with no preconceived ideas of the method he will employ. He must, on the contrary, be familiar by training and experience with a variety of methods all of which he can apply with equal facility after the lesion has been exposed. A study of the immediate mortality following operation for peptic ulcer shows that complications directly attributable to the operation itself, pulmonary complications, and cardiorenal complications have been the three major causes of death. The importance of these three factors varied in different series but in some the complications attributable to the operation accounted for more than two-thirds of the mortality. This is an indication that the proper performance of the operative procedure is an important factor in the immediate and late results.

GASTROJEJUNAL ULCER; RECURRENT ULCER

A study of the results of 17 authors from various countries shows that recurrent or jejunal ulcer follows *gastro-enterostomy* in from 0.9 to 6.9 per cent of the cases with an average incidence of 3 per cent. Berg,⁶ however, states that the

incidence is 30 per cent. A study of the results of 8 authors shows that recurrent or jejunal ulcer follows *partial gastrectomy* in from 0.6 to 60 per cent with an average of 19 per cent. Gatewood, however, in his experience found an incidence of 10 per cent. The operative procedures which have been employed in the presence of this unfortunate complication have been (1) gastro-enterostomy (in ulcer following a primary Billroth I), (2) disconnection of the gastro enterostomy and resection of the gastrojejunal ulcer, (3) disconnection of the gastro-enterostomy, resection of the gastrojejunal ulcer, and gastroduodenostomy or pyloroplasty, and (4) disconnection and gastric resection by the methods of Billroth I or Polya.

It has been impossible for me to appraise from the literature the merits of these various procedures. All of them are serious procedures from the standpoint of mortality and almost all observers have had a higher mortality following these secondary operations than following even the major primary operations. The cause of the occurrence of gastrojejunal ulcer is not altogether clear. It would appear doubtful that the technic of the primary operation (kind of suture material used, etc.) is a major factor in its production, and it would seem that certain individuals have a tendency to ulcer formation beyond the average. This would seem one argument for a very careful consideration of the primary operative procedure.

It is obvious that the type of secondary operation selected in any given case will depend upon the kind of primary operation performed and in some such a way as follows:

A In jejunal ulcer following a primary Billroth I or Polya operation, posterior gastro enterostomy may appear to be the simplest and best procedure. It should be combined with a very careful medical regimen for there is no assurance that another ulcer will not form at the site of the gastro enterostomy.

B In gastrojejunal ulcer following primary gastro enterostomy it may be found at the secondary operation that the original ulcer is apparently completely healed and the pylorus unobstructed. Disconnection of the gastro enterostomy, excision of the jejunal ulcer, and closure of the wounds in stomach and jejunum combined with strict medical regimen may best meet the indications.

C In other cases of gastrojejunal ulcer following primary gastro-enterostomy, one of the following operative procedures may best meet the indications: (a) Disconnection of the gastro-enterostomy, resection of the gastrojejunal ulcer and pyloroplasty, (b) disconnection of the gastro enterostomy, excision of the gastrojejunal ulcer, and gastric resection according to the method of Billroth I or of Polya and its modifications, and (c) large gastric resection at the level of the previous gastro-enterostomy with the Polya type of reconstruction.

D In gastrojejunal ulcer following a primary gastric resection by the method of Billroth II, the disconnection of the gastro-enterostomy, excision of the ulcer and reconstruction by the method of Polya if possible may best meet the indications.

As I have stated, I have been unable to discover from the literature the merits of these various procedures. It is simple to state what may be done in recurrent or gastrojejunal ulcer following various primary procedures, it is far from simple very often to perform the operation when confronted with the actual conditions. A survey of the literature would suggest that the consensus of opinion in this country is in favor of the simpler, more conservative procedures such as disconnection of the gastro enterostomy, excision of the ulcer, and pyloroplasty rather than the larger gastric resections, and with this view I am in accord. But as I have stated in discussing the primary operations for peptic ulcer, one should approach the secondary ulcer without preconceived ideas as to its treatment, rather one should be prepared to perform one of several procedures which best meets the situation.

PERFORATED PEPTIC ULCER

In a paper on peptic ulcer written in 1925, I reported the results of a study of perforated ulcer made by Dr. Floyd B. Johnston,⁸ then one of my associates. The study included 39 cases of acute perforation at the Cincinnati General Hospital and 1,464 cases collected from the then recent literature. In our own series the mortality in cases operated upon up to 12 hours after perforation was 22 per cent, in cases operated upon between 12 and 24 hours after perforation it was 66 per cent, and in cases operated upon over 24 hours after perforation it was 71 per cent. In the 1,464 cases collected from the litera-

ture the mortality in operations after the same periods of time was almost identical, *i.e.*, 22 per cent, 60 per cent, and 73 per cent, respectively. An analysis of the operations performed with the immediate mortality and late results showed the following:

(a) Of 710 patients in whom a simple closure of the perforated ulcer was performed, 254 died—a mortality of 35.7 per cent. Of the 456 who recovered, 365 (80 per cent) reported their late results. Of this number, 25 per cent reported more or less severe ulcer symptoms, of whom 10 per cent required or were subjected to subsequent gastro-enterostomy.

(b) Of 281 patients in whom closure of the perforated ulcer was combined with gastro-enterostomy, 58 died—a mortality of 20.6 per cent. Of the 223 who recovered, 125 (56 per cent) reported their late results. Of this number, 12 per cent reported more or less severe ulcer symptoms, and of these 1.3 per cent were later operated upon for gastrojejunal ulcer.

(c) Of 24 patients in whom closure was combined with pyloroplasty, 3 died—a mortality of 12.5 per cent. Of the 21 who survived, 16 (75 per cent) reported their late results. Of this number, 24 per cent reported more or less severe ulcer symptoms.

(d) Of 41 patients in whom gastric resection was performed, 8 died—a mortality of 19.5 per cent. Of the 38 who recovered, 20 (60 per cent) reported their late results. Of this number, 6 per cent reported more or less severe ulcer symptoms.

I have again collected 3,344 cases of perforated peptic ulcer from the literature. Of this number, 1,929 cases were operated upon from 1 to 12 hours after perforation with 323 deaths—a mortality of 16.7 per cent; 1,157 were operated upon more than 12 hours after perforation with 643 deaths—a mortality of 55.5 per cent. It will be seen on comparing these figures with the preceding that the mortality in acute perforation of peptic ulcer has declined slightly since the preceding figures were assembled. An attempt to analyze this series of cases from the viewpoints of the kind of operations performed, their mortality and late results, has met with only partial success; for in many cases this information is lacking. Such data as I have been able to assemble may be stated as follows:

(a) In 1,271 patients upon whom simple closure of the perforation was performed the primary mortality was 31.7 per cent and good results were obtained in 41 per cent of those who survived.

(b) In 859 patients upon whom closure plus gastro-enterostomy was performed the primary mortality was 22.7 per cent and good results were obtained in 49.4 per cent of those who survived.

(c) In 10 patients upon whom closure combined with pyloroplasty was performed, neither the primary mortality nor the late results are given.

(d) In 154 patients upon whom a gastric resection was performed, the primary mortality was 30.4 per cent and good results were obtained in 75.7 per cent of those who survived.

A consideration of these findings leads to a series of conclusions with which no doubt the reader is perfectly familiar.

1. The time element, meaning by this the elapsed time between perforation and operation, is the most important single factor in determining the primary mortality in acute perforation of peptic ulcer. It is of course understood that the term "time element" is used as a general term and that the factor which in large measure determines the primary mortality in acute perforation of peptic ulcer is the kind and virulence of the viable organisms which escape into the peritoneal cavity following perforation. Should these be virulent streptococci giving rise to a streptococcic peritonitis, the mortality following closure 2 to 4 hours after perforation is, in my experience, higher than following closure 10 to 12 hours after perforation in the case of less dangerous nonvirulent organisms.

2. Neither our own experience nor the experience of others as revealed in the literature indicates that simple closure of the ulcer has been attended with a lower primary mortality rate than closure combined with gastro-enterostomy. Indeed, in general, the mortality following closure plus gastro-enterostomy is lower than that following simple closure. It is difficult, however, to imagine that the addition of a gastro-enterostomy has actually saved lives and it must be presumed that closure and gastro-enterostomy have been performed, in general, upon patients in better condition than simple closure.

3 The idea, often earlier expressed, that perforation of an ulcer cures the ulcer is not borne out by accumulated experience. As indicated above, fully 25 per cent of the patients who survived simple closure of the perforated ulcer reported more or less severe ulcer symptoms a lesser number who survived closure and gastro-enterostomy and gastric resection. A comparison of the late results of simple closure and closure plus gastro-enterostomy so far as they are available does not, however, show a sufficiently striking difference to warrant advocating one operation in preference to the other, and if this is true, the simpler operation would seem the operation of choice. Gastric resection while it appears to have given better late results than either

of the simpler procedures can scarcely be considered as a measure for general adoption.

For the acutely perforated ulcer simple closure would appear to be the operation of choice. If closure results in obstruction at the pylorus, closure should be combined with gastro-enterostomy.

BRITISH MATERNAL DEATHS RISING

More babies are being saved but more mothers lost.

This sentence tells in a nutshell the situation of infant and maternal mortality in Great Britain. The newly established British College of Obstetricians and Gynecologists was addressed a few weeks ago by Stanley Baldwin, former Prime Minister, who remarked that the country did not realize that while during the present century the general death rate had been reduced by about one third tuberculosis reduced by an equal amount and infant mortality by nearly one half the maternal death rate was slightly increasing.

It had been shown that half of the maternal deaths in Great Britain were preventable. That was, said the former Premier, a terrible indictment. It was extraordinary that the country had for so long taken these deaths like accidents on the road as a matter of course. They were in fact a reflection on the intelligence of the people and on humanity.

The London correspondent of the *AMA Journal* who reported this, also reported a recent

meeting of more than 1000 women in London arranged by the Maternal Mortality Committee. Delegates attributed the mother mortality rise to a wide spread condition of malnutrition prevailing during the depression. Lady Barrett, gynecologist of the London School of Medicine for Women suggested as an effective means of dealing with malnutrition the establishment of a dining room for nursing mothers operated in connection with ante partum clinics. The resolution was carried unanimously, as were some others to the effect that allowances should be paid in all maternity cases on the lines of national health insurance that all local authorities should provide a complete gynecologic service, which would include advice on birth control, and that the Minister of Health and the British Medical Association should be asked to receive a deputation urging wider provision of midwifery services and fuller maintenance and development of child welfare and maternity services.

MEDICAL LIFE IN MISSISSIPPI

Those who think that poetry has gone from modern life, especially from the life of men of cold science like the doctors are invited to read a Mississippi County report in the *New Orleans Medical and Surgical Journal*. It can almost be set to music. It runs thus: Dr and Mrs Laurence J. Clark are the proud hosts to a most noted celebrity who came as an abiding guest to their home and hearts at 9:00 A. M. November 2 in the person of a tiny little lady previously unknown to them. She is making her first visit and as they fondly and joyfully welcomed her they asked "What is life?" and her reply was, "Tis to be born."

A helpless baby, to greet the light with a sharp wail as if the morn foretold a cloudy noon

and night, to weep to sleep and weep again, with sunny smiles between, and then?"

In the same report we read that the County delegates to the meeting of the Southern Medical Association in San Antonio Texas will put on a rodeo on the night of the "big show." It appears that Dr. Edley Jones will ride the "bucking broncho," Pierre Robert as a famed matador will fight the wild man, Guy C. Jarratt will administer pasteurized milk and cod liver oil to the little doggies, William Purks and "Señor" with his guitar will serenade the "Señorita" and old Mich Smith will endeavor to "show them the way back home when all is over 'Over There'."

DIAGNOSIS AND TREATMENT OF ANEMIA

STUART L. VAUGHAN, M.D.

Buffalo General Hospital and University of Buffalo

For physicians engaged in the actual practice of medicine it is extremely important to view all phases of a subject in proper perspective. This is difficult and no less so with the subject of anemia than with any other. This difficulty is forgotten by many writers, including some of the leaders in hematology who, in their laudable enthusiasm over special issues, often assign to them, by implication at least, an unwarranted importance. We have long since learned that a reactionary or ultra-conservative attitude is not conducive to progress, because ideas which have seemed almost fantastic when first reported have led frequently to revolutionary advances. On the other hand, an ultraradical attitude is apt to result in a loss of the good from the older order and the adoption of many new procedures which eventually prove valueless.

In this discussion the aim will be to seek a course midway between these two attitudes in bringing out points relating to diagnosis and treatment which have seemed most important to the author. With due regard for the complexity of many of the issues involved, it may be said at the start that for the majority of cases the procedures of proven value are often simpler than we are led to believe.

The problem that first presents itself concerns the kind of diagnosis which will be most useful to indicate prognosis and treatment. If we consider anemia not as a disease but as a manifestation of some underlying disorder, it becomes clear that the diagnosis of greatest importance is that of the main anemia-causing factor. In the present state of our knowledge it seems wise to consider such factors broadly as disorders, diseases, and deficiencies which may be readily recognized.

With these considerations in mind it is possible to attack the problem of etiologic diagnosis with some assurance of success. In a series of 191 consecutive cases recently studied, 79 per cent could be classified on the basis of what was thought to be the major etiologic factor. The classification is given in Table I.

It will be noted that 54 per cent were grouped under the heading of active causes of which hemorrhage and infection accounted for the greatest number. One might be surprised at this large percentage since modern literature tends to minimize this group. Twenty-five per cent were grouped under passive causes or nutritional deficiency. Pernicious anemia cases fell in this group. In 21 per cent the cause was not classified, although a definite or probable diagnosis was made in half of them.

In other words, the great majority of cases could be classified in such a way that the primary therapeutic indication seemed rather simple. In only 11 per cent were we more or less completely in the dark as to this.

With our objective before us, the next question concerns the most direct method of arriving at the diagnosis. The recent overemphasis of modern technical laboratory procedures to solve clinical problems has resulted in some loss of confidence in the history, physical examination, and simpler accessory measures. This seems unfortunate, but with the present trend back to common sense there is hope that this situation will correct itself.

TABLE I.—ANEMIA CLASSIFIED AS TO CAUSE

	No. of cases	Per cent
I. Active causes	103	54
1. Hemorrhage	44	23
2. Infection	21	11
3. Leukemia	12	6
4. Malignant tumor (hemorrhage not evident)	9	5
5. Chemical poisoning	7	4
6. Nephritis with nitrogen retention	6	3
7. Splenic hyperactivity and related phenomena	4	2
II. Passive causes (nutritional deficiency)	47	25
1. Pernicious anemia syndrome	36	19
2. Deficient food intake	7	4
3. Deficient food assimilation (achlorhydric)	4	2
III. Cause not classified	41	21
1. Definite diagnosis made	6	3
2. Probable diagnosis made	14	7
3. Multiple factors	18	9
4. No cause found	3	2

In the series of cases studied a reasonably complete history with fairly definite objectives was found, by itself, to be diag-

nostic or practically so in 35.1 per cent (Table II). Considered in conjunction with the physical examination the percentage rose to 42.9. Adding the results of the blood count with examination of the stained film the total reached 61.8 per cent.

Naturally, other measures were carried out and they were often of definite assistance either in confirming the diagnosis or in excluding other possibilities. In the remaining group of 16.8 per cent of cases, where a definite etiologic diagnosis was made eventually, the diagnostic procedures varied. They included tests for occult blood in feces, gastric analysis, x-ray, surgical exploration, bacteriologic examination, chemical determinations, biopsy, results of therapeutic procedures, and necropsy.

In brief, there was only about one-fifth of the cases in which a diagnosis on the basis of major etiology could not be made by the simplest of well-recognized clinical procedures.

Of great interest to the author was the fact that no test in this group could be called new. However, there is one that has acquired a new importance. That is gastric analysis as applied to conditions other than pernicious anemia.¹ Abnormality of gastric secretions as evidenced by an absence of hydrochloric acid seems to offer a logical explanation for nutritional deficiency in cases where no other anemia-causing factor can be found.

One can hardly leave the question of diagnosis without some mention of the classifications of anemia based on the various combinations of cell number, cell size, and saturation with hemoglobin. These

indices involved. They offer very little information from the etiologic point of view, except in the group where the cells are of large size. Practically all pernicious anemia cases and very few others will be found in this group. But even here these tests merely confirm observations made on the stained blood film. On the other hand, this type of study undoubtedly has very definite value. It serves to emphasize the importance of macrocytosis in the diagnosis of pernicious anemia. It affords an excellent method of analyzing certain features of the blood state. It shows that the same major etiologic factor affects the blood differently in different cases, thus directing attention to possible secondary factors. Whether or not this will be of aid in indicating the form of treatment will be discussed later. It is certain, however, that its part will be comparatively small when considered in the light of the major therapeutic indications and it is these that deserve notice.

As pointed out earlier, 79 per cent of the cases in this series were classified on the basis of the major cause. Whether or not such a high percentage would be found in the general run of anemia cases cannot be said, but surely it would be high. The primary therapeutic indication is to attack the cause. When the cause can be removed, complete recovery from anemia follows in practically every case. It is interesting that accessory treatment with iron, liver, etc., seems of slight importance in this group, since recovery was almost equally rapid as far as could be determined in the cases that did not receive such treatment.

Where complete removal of the cause is not possible, but some alleviation is effected, definite improvement in the blood occurs. Accessory measures seem to be of value here.

When the cause cannot be removed or alleviated in any way, the results of treatment by any measures are more discouraging. However, improvement is to be expected in some cases (24 per cent in this series) by accessory measures. These measures should be used not so much to improve the blood state for itself as to elevate the patient's resistance and to support him while a temporary cause is active. This is particularly important in anemias due to infection and chemical poisoning. Besides animal protein and iron as indicated nutritional substances, transfusion of blood is often of great value.

TABLE II.—ANALYSIS OF DIAGNOSTIC PROCEDURES IN 191 CASES

Procedures	Diagnostic		Suggestive		Indefinite		Misleading	
	Cases	Per cent	Cases	Per cent	Cases	Per cent	Cases	Per cent
History alone	67	35.1	69	30.9	60	36.2	2	1.0
Physical examination alone	59	30.9	61	31.9	63	35.5	5	2.6
Blood examination alone	55	28.9	63	33.0	63	35.5	5	2.6
History or physical examination or both	82	42.9	60	31.4	45	23.0	4	2.1
One or more of the above three	118	61.8	28	14.7	41	21.4	4	2.1
All available procedures	156	81.7	14	7.3	21	11.0		

have been so popularized by the work of Osgood,² Haden,³ Wintrobe,⁴ and others that it would seem that no case study is complete without determining the various

In passing it should be said that transfusion is indicated in any anemia, whatever the cause, when the condition of the patient is so serious as to constitute an emergency.

In regard to anemias dependent upon nutritional deficiency little need be said of the therapeutic indication. Where the deficiency is in hemoglobin, iron and diet rich in animal protein are indicated, of course. In pernicious anemia, liver or some analogous substance must be supplied. It is the technic of the administration that deserves special consideration.

Iron should be given always in conjunction with a diet containing an adequate amount of protein of animal origin, such as lean meat. The author's own experience supports the evidence of many workers that the best results follow oral administration of any form of iron which will be assimilated. It is extremely effective when used in sufficient dosage. Because of its economy and solubility, iron and ammonium citrate is the favorite. It is well tolerated in doses of 2 gm. three times daily, preferably in the form of a 50 per cent solution in an agreeable vehicle. In properly diagnosed cases the results are uniformly specific and marked improvement is noted within the first month.

As to liver, almost any form is effective. We all know the difficulties involved in long-continued oral administration, however, and the advantages of intramuscular injection outweigh the disadvantages. The following procedure is highly effective: The pernicious anemia patient in relapse is given one dose of intramuscular extract* daily for three successive days followed by one injection each week until there is complete remission. Thereafter the interval between doses is lengthened according to the needs of the patient. In a group of cases, uncomplicated by cord degeneration and observed for at least two and one-half years, the average interval was about one month. It is obvious that they must be examined thoroughly at least once a month and advised to report immediately if they develop any subjective symptoms, particularly gastro-intestinal upsets.

* One dose is considered here as equivalent to 3 c.c. of Lederle's extract.

The use of hydrochloric acid has been of little apparent value.

Patients with cord changes are treated more intensively and the results are often remarkable. Improvement may be both subjective and objective.

From the point of view of therapeutic indication perhaps the most enticing problem concerns those cases in which no definite etiologic factor can be determined after a thorough search. It is in this group that careful study of cell size and hemoglobin saturation seems to have its greatest potential value. While in the end the procedure must be in the form of a therapeutic test, these determinations will indicate the logical treatment to be tried first. Those in which the average cell size is larger than normal may be given liver in the manner described for pernicious anemia with considerable hope of success. Of the remainder, those with low hemoglobin saturation usually respond to iron. In those having hemoglobin saturation more or less normal, one might think that a combination is indicated. The author's own experience, however, has been that iron alone is often extremely effective. A not unusual observation has been that shortly after the treatment is started, the red cells increase in number and size, so that an actual hemoglobin unsaturation results with the subsequent course exactly as in the low hemoglobin saturation group.

In conclusion the author wishes to emphasize the importance of a sensible attitude in approaching the anemia problem. Considered in its proper light, anemia is a symptom complex. To find and attack the underlying cause is the chief objective. The most valuable diagnostic procedures are old and tried and the therapeutic indications are clear-cut in the majority of cases. When an etiologic diagnosis is impossible, the newer methods may suggest the type of therapeutic test to be tried first.

SULPHARSPIH NAMINE. ITS USE AND STATUS IN NEW YORK STATE

ALBERT PFEIFFER, MD

*Director Division of Social Hygiene
New York State Department of Health Albany*

SOCIAL PHASE

The prevalence of syphilis and the military and public health necessity of its control in 1917 demanded that governmental agencies should take an active interest in providing diagnostic and treatment facilities which necessarily included the distribution of the arsphenamines to all practitioners. Because of the chemical composition of arsphenamines and because of their pharmacological action involving potential dangers to life, this was a grave responsibility, but still in keeping with the policy of state governments, which permitted the distribution of biologic products to all licensed physicians.

The distribution could not be limited to skilled specialists in syphilology nor were the specialists available in such numbers as adequately to care for the patients needing public aid. For the control and ultimate eradication of syphilis, public health necessarily demands that adequate diagnostic and therapeutic facilities shall be available to all the people, in the rural as well as in the urban communities. This emphasizes the importance of the general practitioners, the men on the frontiers who see over 60 per cent of the patients with syphilis first and who should make an early diagnosis and institute immediate treatment.

The management of syphilis—the master disease—is so many sided and complicated that specialists should frequently be consulted for the best interests of the patient and the community. Provided there is trust, confidence, and close co-operation between the practitioner and the specialist, much of the routine treatment can be conducted by the general practitioner. Popularizing the treatment of syphilis does not deter in the slightest the importance and place of the specialist. Whether the patient is in a hospital bed, special service clinic, or the private practice of a surgeon, internist, pediatrician, or other specialist the management is best carried out in consultation with, or under the direction of, the syphilologist. The control of syphilis and its possible eradication appears to be a

community problem analogous to that of tuberculosis and mental diseases. Two thousand physicians are constantly in our state institutions and a multitude of patients in general hospitals and welfare homes through various ailments attributed to syphilis. This emphasizes the economic and social importance of syphilis. We estimate that approximately 60 per cent of syphilis cases today in upstate New York are treated at public expense and the taxpayers are little interested in academic discussions or in anything except the greatest value for the least expenditure of public funds.

Any effective drug suitable for the greatest number of physicians or which insures adequate treatment for the largest number of patients is of great value. Sulpharsphenamine meets these requirements. Many are at clinics today because of irregular, intermittent, and inadequate previous medical care and when it becomes necessary for public money to be expended for cases which could have been prevented by adequate early treatment, it seems a paramount right of the people and the duty of health officials to prevent this condition with its loss of usefulness to the individual and the large expenditure of public funds.

Arsphenamine is unsuited for general use, and until comparatively recently neoarsphenamine was rather an unreliable product varying greatly in composition and stability. Variations of 300 per cent in parasiticidal power have been shown and confirmed by other investigators,¹ while Roth showed that 25 to 30 per cent of commercial neoarsphenamine deteriorated in the ampule in the course of time. It was particularly unstable when exposed to air and agitated in forming a solution, which is common practice. The pain and local necrosis often seen resulting from faulty injections were a serious disadvantage.

When Voegtlin and Johnson produced sulpharsphenamine in the Hygienic Laboratory of the United States Public Health Service in 1922, it was thought that this

preparation might solve some of the difficulties, particularly in that it would provide a stable chemical compound, quite uniform, high in arsenic content and in therapeutic value, readily soluble, relatively nontoxic by laboratory experiments, and not destructive to the local tissues. The latter factor had a striking appeal. An arsphenamine that required no neutralizing and that could be given intramuscularly in 1 c.c. of distilled water was of inestimable value and immediately suggested the possibility of getting the vast majority of infected patients under early, lengthy, and effective treatment.

Manufacture was at once started in 1922 at the author's request in the Massachusetts State Laboratory and the resulting product easily passed the standard toxicity tests of the United States Public Health Service. This was placed in 20 clinics and in some state institutions for trial as to tolerance, therapeutic properties, dosage and concentration of solution for both local and intravenous use. About 15,000 gm. were distributed and after two years' trial it was pronounced a reliable and effective preparation.

This constituted what is believed to have been the first extensive trial of this drug.² The size of dose varied from 0.3 to 0.9 gm. and the drug was given intramuscularly and intravenously. Some clinicians got few, if any, reactions, and continued the use of 0.9 gm. while others got satisfactory results with smaller doses averaging 0.6 gm. intravenously and 0.3 to 0.45 gm. locally. It was found that for local treatment a dose limited to 0.45 gm. in 1 c.c. of distilled water was well tolerated in a large percentage of cases depending upon the temperament and type of patient and upon the personality of the clinician. Reactions were on the whole less than had been previously experienced with arsphenamine. With continued experience over several years it was found that 0.45 gm. was a dose both comparatively safe and effectively therapeutic when given either locally or intravenously.

As a result of this experience the Division of Social Hygiene of our State Health Department in 1925 began the free distribution of sulpharsphenamine to hospitals, state institutions, clinics, and practicing physicians for the treatment of patients unable to pay proper fees. Until this time comparatively little assistance had been given in the way of supplying drugs free

to physicians as the available arsphenamine went almost entirely to established clinics. To date, May 1, 1934, we have given out 159,034 gm. of sulpharsphenamine (since 1925), 100,949 gm. of arsphenamine (since 1919), and 41,778 gm. of neoarsphenamine (since 1932), and incidentally 340,110 c.c. of bismuth subsalicylate (since 1931), 36,050 c.c. of iodobismitol (since 1933), and 30,053 gm. of tryparsamide (since 1931).

Our experience with sulpharsphenamine has been satisfactory and quite at a variance with that of some other observers as to its value and dangers. A statistical study often shows a different picture from one's impressions; for this reason the author has assembled all the active case histories in three clinics where sulpharsphenamine has been used exclusively and where the records have been such that dependence could be placed upon them. This study deals with reactions as they are the main factor under discussion, for surely there can be little controversy regarding its therapeutic value. These case histories were tabulated and charted by the Division of Vital Statistics of the State Health Department.

Twenty-nine thousand five hundred ten injections of sulpharsphenamine were given to 920 patients in three clinics situated in Albany, Utica, and Rochester, referred to hereafter as Clinics A, B, and C, respectively. All but 693 treatments were given intravenously in doses varying from 0.3 to 0.6 gm. Some acute cases were treated twice a week and for a time all patients at one clinic received 0.6 gm. twice a week. Now 0.45 gm. is usually given and apparently there are equally as good therapeutic results and fewer of the severe reactions. The intramuscular injections were given mainly in special cases, e. g., congenital, central nervous system, and previous reactors. A few early cases were treated by this route throughout, and while the author's study is not complete, it is thought that this is the preferable route when patients will tolerate it. Intramuscularly, the drug seems to be quite as effective as arsphenamine; intravenously, in early cases and considerably more so in the late cases. Little reliance should be taken on the statement that has been made by some authors (a sort of apology) that the only reason for its use in congenital syphilis is its ease of administration.

Chart II tends to indicate a personal, or possibly prejudicial element in the records of the

clinicians, one specializing in the recording of one reaction, while others emphasized different reactions; e.g.: Clinician A noted taste, smell, nausea, and vomiting. Clinician C had an urinalysis before each treatment.

A remarkable similarity is noted under pruritus or slight dermatitis. The New York clinics had practically the same rate with sulpharsphenamine as the Co-operative Group had with their combined arsphenamines.

The Co-operative Group did not note loss of weight, lassitude, malaise, and so on—possibly indicative of intolerance.

CHART III

The co-operative clinic group's mild treatment reactions represent "the minimum of those occurring." The rates of the different clinics vary

Chart III.—Mild treatment reactions to sulpharsphenamine and other arsenicals, per 1,000 injections, among patients treated or observed for six months or more.

from 2.4 per 1,000 injections to 18.54 per 1,000. While this chart may not represent the "maximum," it constitutes a fairly true picture. Refraining from eating before treatments has not been emphasized in sulpharsphenamine therapy. The gastro-intestinal and vasomotor figures are probably higher than good technic would warrant. Vasomotor reactions under usual conditions are rare.

It is rather surprising that again pruritus is about the same for our study as for all the arsenicals in the co-operative study. A physical examination including an urinalysis before each treatment in Clinic C no doubt accounts for the high rate of transient albumin. As previously mentioned, malaise, loss of weight, and so on, formed the "other and unspecified" reactions not recorded in the other study.

CHART IV

In every instance with the exception of purpura (which only occurred six times) the rates were less than those from the combined arsenicals in the Co-operative Group. There were no aplastic

anemia, cerebral hemorrhage, or acute yellow atrophy of the liver.

Chart IV.—Severe treatment reactions to sulpharsphenamine and other arsenicals, per 1,000 injections, among patients treated or observed for six months or more.

CHART V

Osborne's rate, 12.28 with but 896 injections, suggests a selected group which is obviously too small to form definite conclusions. The Co-operating Clinics' rate 3.54 with but 7,912 injections is open to the same criticism.

The Navy was a special group hardly comparable with regular civil clinic patients. The Co-operative Group gave 0.6 gm. as a maximum dose but no data as to intensity of the treatments.

Chart V.—(A) Severe reactions per 1,000 injections of sulpharsphenamine. (B) Number of injections of sulpharsphenamine.

Most of the treatments were under 0.6 gm. The author does not believe that a true picture can be presented on the basis of the material studied thus far. Of the six cases of purpura in the New York study, four occurred in Clinic A that

had the smallest number of treatments. It seems reasonable to believe that some factor other than the drug per se is responsible for this type of reaction—an impurity, possibly an idiosyncrasy or some other contributory cause such as grippé or alcoholism or a combination of these factors.

A PENAL INSTITUTION STUDY

During 1929 to 1932, a penal institution in the state was supplied with 5,900 gm of sulpharsphenamine, 8,198 injections were administered, the average dose being 0.72 gm. The plan followed at first was to give ten weekly intravenous injections of 0.9 gm, two such courses being administered each year. No bismuth or mercury was used. Two thousand eighty-six of these treatments were given. The reactions recorded were:

Dermatitis mild 3
Transient albumin 2
Dermatitis severe 2

Jaundice 1 ending fatally from acute hepatitis.

Several of the patients exhibited a peripheral neuritis.

Late in 1930 the dose was reduced to 0.6 gm as a maximum size with a marked reduction in mild reactions. The final total of severe reactions for the 8,198 injections averaging 0.72 gm was: Dermatitis (mild and severe) 5, a rate of 0.01 per thousand, deaths, 3, a rate of 0.37 per thousand. The deaths were:

1 Male, age 33. Late syphilis, treatment 0.6 gm (2), 0.9 gm (6) other therapy, none, cause of death: acute hepatitis.

2 Male, age 40. Late syphilis, treatment 0.6 gm (8), 0.9 gm (12) bismuth salicylate (20), cause of death: acute nephritis, pernicious anemia.

3 Male, age 28. Late syphilis, treatment 0.6 gm (4), 0.9 gm (16), bismuth salicylate (5), cause of death: acute nephritis, uremia.

From the intensive sulpharsphenamine therapy with its large doses, it was rather surprising that the rate from dermatitis was so low—0.01 per thousand—is compared with 0.81 and 0.90 for neoarsphenamine and arsphenamine of the Co-operative Clinic Study. The single jaundice case gave a rate of 0.12 and there were no cases of blood dyscrasia.

Jonathan Hutchinson in the preface to his treatise on syphilis stated that "the results of clinical observation and those of experimental and microscopical research should always be considered together. It is not for good that either should be allowed to rank as a court of appeal from the decisions of the other. There are

special liabilities to error which are incident to each, and when their conclusions differ, the case should be tried over again."

An outstanding example of non-logical conclusions drawn from laboratory experiments is the work done by Fordyce and Myers on tryparsamide, reported in 1925.⁴ The conclusion was reached that tryparsamide was an inferior drug compared with salvarsan and silver salvarsan in the treatment of central nervous system syphilis. Since that time experience and mature judgment have proven the fallacy of the conclusions derived from this laboratory experimental work. The almost instant clinical improvement in so many of the cases, the feeling of well-being, the change in mental conditions and gain in weight is miraculous. Sulpharsphenamine was dealt with earlier in the year by the same workers with equally favorable results.⁵ (?)

Osborne *et al.*⁶ by a simple procedure attempted to prove the fate of the arsphenamines in the animal body. Substances reputed to have been crystals of arsenic trisulphate were seen and the tests were supposed to prove that the liver had not "metabolized" sulpharsphenamine as effectively as arsphenamine or neoarsphenamine. There is considerable doubt that arsenic can be split from its linkage with carbon by the process used to enable the sulphite to be formed. The experiments did not prove that the arsphenamines were metabolized in a given tissue.

Although from Ehrlich down to the present, biochemists and pharmacologists have tried to find out what it is that takes place in the body when an arsphenamine is injected, the metabolism of this process still remains more or less a mystery.

Modern research in the fundamental problems of chemotherapy requires an extensive organization of specialists, including a well equipped experimental laboratory and a picked personnel of chemists, pharmacologists, bacteriologists who must work in conjunction with the clinicians. Ehrlich's original laboratory was so organized and ample funds were available. His successor, Kolle, is manufacturing a preparation under the name of myosalvarsan which is chemically and pharmacologically similar to the American sulpharsphenamine.

Arsphenamine, neoarsphenamine, and sulpharsphenamine have all caused the same types of reactions terminating fatally in rare instances. Neoarsphenamine and sulpharsphenamine have been regarded as

more likely to cause the blood dyscrasias than the old product arsphenamine. These drugs have a very similar formula and it might be so but to what extent these two drugs per se have been responsible and how much has been due to the special sensitivity or idiosyncrasy of the individual patient, or due to other factors such as alcoholism, influenza, or other toxemias or inorganic adulterations, it is impossible at present to say. The arsenic content of different batches of both neoarsphenamine and sulpharsphenamine has a slight variance owing to the presence of chemical impurities. When severe blood dyscrasias occur with any of the arsphenamines, it is usually after the first, second, or third treatment; and the sudden occurrence and rarity of these conditions point toward other factors rather than to the drug itself.

Occasionally a certain lot of sulpharsphenamine will give a consecutive number of vasomotor reactions (which is a rare type of reaction in the use of this drug), and these reactions often occur at the beginning of the injections. The same batch has proven experimentally on animals to be perfectly safe. Fortunately this is a rare occurrence but when it happens in the field among practitioners, it is alarming and not only leads to complaints about the particular drug used but prejudice against the manufacturer as well. As a safeguard and further check the author's clinic has recently adopted a system of testing a sample lot before ordering a large supply of a particular output.

Arsphenamine is more colloidal than neoarsphenamine and sulpharsphenamine

still more so; they are, therefore, regarded as being slower to act on infectious lesions of syphilis.

Over a decade ago Stokes⁷ published the effect of an arsphenamine on a lesion of a patient with primary syphilis. Sulpharsphenamine 0.4 gm. was injected epifascially, causing no discomfort, and dark-field examinations were made each hour.

After 4 hours a change was noticed in motility and in the number of spirochetes and none could be found after 8 hours. After 11 days the chancre had entirely healed.

Clinically lesions respond at about the same rate with all the arsphenamines but a cure depends upon the follow-through effects of a drug over a comparatively long period to get the last spirochete. Sulpharsphenamine fulfills the public health requirements more than any other drug and deserves a more thorough scientific investigation and evaluation than has been given.

SOLOMON'S R STILL GOING STRONG

When Solomon recorded that "A merry heart doeth good like medicine," he wrote a prescription still in wide use by the medical profession. Doctors and nurses attending the sick, according to a writer in *Life and Health*, realize how valuable it is as an aid to the recovery of patients to have their minds at ease concerning their

symptoms. A doctor's diagnosis is always presented in the most hopeful setting to the patient. Hope for the better is readily seized upon by everybody except the most despairing. That hope is a buoyant and sustaining element in the struggle. As long as it is retained, it greatly adds to the fighting spirit and maintains courage.

STORY OF THE WISE RATS

A story in the *Chicago Tribune* tells of a city in Southern California which tried to get rid of its rats by giving them corn treated with thallium sulphate. This chemical is a poison, as we all know, but is also used in small doses to remove hair from the body. The Mexican peon population, knowing nothing about the thallium

sulphate, stole quantities of the corn and made it up into the dishes that delight the Mexican palate. Within a few days every one who had eaten the poisoned corn was hairless and seven had died. Thirty-five, who were arrested, confessed stealing the corn. But the rats refused even to taste it.

RESULTS OBTAINED IN A RELATIVELY SMALL COMMUNITY USING THE SINGLE DOSE TOXOID METHOD FOR IMMUNIZATION AGAINST DIPHTHERIA

H. J. SHELLEY, M.D.

Middletown

ABSTRACT

This brief paper is presented not as an ultra-scientific dissertation but, rather, as an attempt to show why larger numbers of children can be immunized against diphtheria by the use of the one-dose toxoid than by the use of the two-dose toxoid or by toxin-antitoxin.

The fact that Middletown stands at the head of the list of all communities in New York State over 10,000 for the greatest number of children under five years immunized against diphtheria has caused many inquiries to be brought as to the reasons for this. The City's Health Department, in which the author is an officer, is proud of having achieved the record of 92 per cent.

A discussion of the details of the City's last campaign ought perhaps to be preceded by a mention of some of the difficulties encountered in this conquest of diphtheria. Notwithstanding the almost universal cry from physicians that health authorities are taking bread from their mouths by inoculating children in clinics, the fact is brought clearly into relief that the doctors themselves immunize an almost negligible number in our City even when the Public Health Nurse refers children directly to them rather than to the free Clinic.

After a number of years of experience it is the author's conclusion that if the community is to be protected against diphtheria, then the public health workers must do the job. The quiescent opposition of physicians no less than the indifference of parents makes this work discouraging and slow.

As to the matter of numbers of immunizations completed, it will not do to lose sight of the fact that in protecting John Smith of the millions, Josephine Gotrock of the four hundred is also being protected, for every child immunized increases the ratio of safe contacts associating with the children whose parents do not believe in "having those poisons" injected.

Up to 1933 the Department's methods were about the same as for nine years previous; i.e., toxin-antitoxin clinics were

held in the Board of Health rooms every Saturday at nine and there was used the three-dose toxin-antitoxin mixture distributed by the New York State Department of Health. No bad reactions of any kind followed the administration of approximately 15,000 doses.

While this program was fairly satisfactory from the standpoint of getting children inoculated, nevertheless the "Big Bad Wolf" made considerable trouble in that invariably there was a number of children who never returned for the second and third injections. Many parents believed one dose gave more or less protection; moreover, there were many families who moved from the City or from one district to another within the City that the Public Health Nurse was never quite able to catch up with them. These lapsed cases caused much confusion in the records as well as a waste of valuable time.

Early last year immunization work dragged and it was discovered that the Department's results were even less satisfactory than for the corresponding period of 1932. Inasmuch as it appeared that there was the necessity of doing something different, the staff began to conduct a more intensive campaign—more visits to families and to doctors, five-minute talks in the theaters, literature in every home whether or not there were children there, Metropolitan agents checking in their field, and so on. This campaign obtained only six new immunizations.

The staff changed, with many misgivings, to the two-dose toxoid; it was realized that any pronounced reactions would bring severe criticism from the medical profession and from the laity. However the results indicated success, whether simply because of the novelty or owing to the advantage of one less trip to the Clinic, it is difficult to say.

The next move was a radical one to undertake in a small city with a Board of Health budget pared to the bone and no slack to take up if expenses ran over. For, to change from a free immunizing product

to one which is relatively expensive, was an item from the financial standpoint. But the staff did change. Early in October was begun the use of the one-dose alum-precipitated toxoid Squibb.

The results were immediately gratifying. The author feels certain the present high record could not have been achieved had the use of the three-dose toxin-antitoxin, or even of the two-dose toxoid, continued.

From the angle of protecting larger numbers of children it is hardly necessary, of course, to point out the advantages of the one-dose agent. It cuts clinic work two-thirds, it obviates home nursing visits to bring children back for second and third doses, and, in the author's opinion, also reduces the number of home nursing visits required to bring children in to Clinic at first.

There will always remain in all strata of social positions an appreciable number of parents who would like to have their children immunized but who are lazy and will never bring them to Clinic or to family physician of their own accord. With this group it was decided to do as Dr. Bundesen of Chicago claimed to have done, in a paper read at the American Public Health Convention in Indianapolis. That is, he inoculated children in the homes. Personally, the author had always considered this poor practice, but after hearing Dr. Bundesen's version of it, he had prepared a survey of the Middletown children under five who were still unimmunized. The number was large enough to be interesting, so the latter part of the year he went into the homes with the one-dose toxoid and treated a sufficient number to put Middletown on the map for 1933. The total number of immunizations for the year was 402. This marked an increase in percentage of immunized children under five years from 87 per cent in 1932 to 92 per cent in 1933.

As to the degree of protection afforded by the one-dose toxoid, authorities seem to

be at some variance, as they are on most medical subjects. Possibly some of these differences lie in the fact that the various workers have used different products and of varying antigenic potency.

Concerning the immunizing value of diphtheria toxoid alum precipitated, workers from Alabama—Graham, Murphree and Gill—make these comments:

The results of immunization of children indicate clearly that a single injection of the alum precipitated toxoid results in immunity in a high percentage of cases. A single injection appears to be as effective as two or three injections of the best unprecipitated toxoid. The group of children who are known to have been strongly Schick positive prior to the injection of toxoid yielded 92.4 per cent completely Schick negative results from two to six months later.

It seems plausible to explain the effectiveness, as an immunizing agent, of the precipitated toxoid on the basis of its relative insolubility. It is absorbed slowly, less antigen is lost by rapid excretion, and there is a consequent prolonged antigenic stimulation.

Precipitated toxoid has several advantages over the ordinary toxoid. Foremost, of course, is its greatly superior antigenic action. For practical field work in the prevention of diphtheria, the value of a single injection needs no comment.

Reactions, on the whole, either local or general, were no greater or more frequent than would be expected from ordinary toxoid in similar groups.

And so, down in Middletown the Health Department is now recommending the one-dose toxoid for all children from six months to five years of age. In the older age groups we recommend the old toxin-antitoxin. Also, we pay no attention to the ignorant wail that the inoculations should not be given in summer as it is too hot, nor to the equally unfounded objection that it is too cold in winter. Our diphtheria prevention work goes on month in and month out and we are hoping that by the use of the one-dose toxoid to raise our percentage of immunized pre-school children another few points this year.

35 SOUTH STREET

MICHIGAN HOLDING THE FORT

In spite of the famous "Detroit Plan," the Michigan State Medical Society, at its last meeting, voted not to experiment with the mutual health service plan presented by the committee on economics. The president of the Society says in a signed statement in its *Journal* that the decision reflects the general sentiment of the profession throughout the state and "demonstrated in no uncertain manner that we, as practicing physicians, desire to continue in the traditional

way to maintain the physician-patient relationship, our independence, the control of our practice, and the opportunity to succeed individually according to character, energy, and merit, receiving such remuneration—often meager and inadequate—as our patients can give us. We prefer this to regimentation and its uncertainties, a greatly increased amount of medical work, a more regular income and possibly—though here opinions vary—a much more remunerative one."

them can be avoided by a plan of procedure which differentiates clinically the benign from the malignant ulcer by its reaction to treatment within a short period of time. The details of the plan which we have adopted to accomplish this purpose will be given shortly.

One other factor besides the danger of malignancy makes the medical treatment of certain chronic gastric ulcers unsatisfactory, *viz.*, the adherence of the ulcer base to a neighboring solid organ. This is apt to occur in large lesions from the location of the ulcer along the lesser curvature. If the ulcer becomes firmly adherent to a

densely adherent to the pancreas which probably accounted for recurrence under a satisfactory medical régime.

In order to avoid these pitfalls in the treatment of chronic ulcers of the stomach, we have evolved the following method of handling such patients in our clinic, based partly upon procedures reported from other clinics. After the localization of the ulcer in the stomach by x-ray, the patient is given strict dietary treatment in bed. We usually use the Sippy régime with alkaline powders. The symptoms must recede within a few days and within two weeks they must practically disappear, including occult blood

Fig. 1.

solid viscus, usually the pancreas or liver, then with healing its base cannot contract down properly. As a consequence, the newly formed mucous membrane has to spread over a large connective tissue base where its blood supply is poor. Such an ulcer, even after it is healed, easily breaks down again. This adherence of the ulcer base is an important cause of refractoriness to medical treatment and of recurrence. Under these conditions, continuation of medical treatment is futile and operation gives much more satisfactory results than attempting to keep the patient comfortable by repeated strict dietary régimes.

J. R., aged 50, an intelligent orderly in the hospital, has had ulcer pain related to meals and relieved by soda for four years. Physical examination negative. Roentgenographic examination showed a penetrating ulcer on the lesser curvature of the stomach. Strict medical régime relieved all symptoms, but they recurred four months later with a persistent niche roentgenographically. At operation the ulcer base was

Fig. 2

from the stools if present. At the end of three weeks, a second roentgenographic examination is made and at this time we decide on further therapy. If the symptoms and occult blood have disappeared and the ulcer niche shows a very considerable decrease in size (usually at least 50 per cent), then it is proper and usually advisable to continue medical treatment, usually changing to a smooth diet and allowing the patient to go home.

W. I., aged 56, has suffered repeated exacerbations of ulcer pain for twelve years. A recent

attack was associated with major hemorrhage for the first time. Physical examination was negative. Roentgenographic examination showed a penetrating ulcer on the lesser curvature. (Fig 4.) The stool was strongly positive for occult blood. On strict medical regime, the patient became symptom-free. The occult blood disappeared from the stools, three weeks after the first roentgenographic examination this was repeated showing great decrease in the size of the niche. (Fig 5.) Consequently the patient was put upon ambulatory medical treatment which was checked in two months by another gastro-intestinal x-ray examination, showing complete disappearance of the niche

But if ambulatory medical treatment is adopted, the physician must continue to follow the patient roentgenographically un-

A. D., aged 46, has had typical attacks of ulcer pain for eight years. Two episodes of hemorrhage have occurred. He has lost 40 lb. in weight during the last year. Roentgenological examination revealed an enormous penetrating ulcer high on the lesser curvature. From the size of the lesion and the extensive weight loss, a malignant ulcer was strongly suspected. He responded rapidly to medical treatment, reducing the huge niche to about a quarter of its initial size in three weeks. Succeeding x-rays showed further healing until a small V-shaped defect remained. This did not disappear, but on subsequent examination began to enlarge again with the return of symptoms. He was then operated upon before the ulcer again became large. The cause of the recurrence was found to be adherence of the ulcer base to the liver.

Fig 3

Fig 4

til the lesion has healed completely. On the other hand, if the patient cannot be made symptom-free, if the ulcer at the end of three weeks does not show considerable diminution in size, or if symptoms recur, then unless the patient is definitely a poor risk, surgical intervention should be instituted. Even after spectacular improvement in a very large ulcer, if the niche starts to enlarge again under treatment, the patient should be operated upon rather than to wait until it has attained a large size again.

The fact that the ulcer crater begins to increase in size under treatment is due to some condition which makes medical treatment unsatisfactory, usually either malignancy or adherence of the base. When the ulcer is malignant, there is often considerable symptomatic improvement and there may be a definite decrease in the size of the niche. Usually, however, it is easy to determine at the end of three weeks in these cases that the diminution in the size of the niche is not satisfactory. Such cases should be operated on then with the loss of only a month from the time when they are first seen and while they are frequently showing considerable symptomatic improvement.

C. W. A., aged 62, has had ulcer pain for seven months. Physical examination negative. At his first visit to the clinic he was put on an ulcer

dietary régime and arrangements were made for roentgenographic examination. The latter showed a penetrating ulcer on the lesser curvature of the stomach. When he returned to the clinic after the ex-ray examination (9 days after his first visit) his symptoms were entirely relieved so that he objected strenuously to coming into the hospital. Three weeks after the first roentgenographic examination this was repeated. Although one view seemed to show considerable decrease in size, the ulcer niche was really little smaller than originally. Surgery was advised and accepted. The ulcer at operation had no characteristics to distinguish it from a benign lesion, but microscopically it was definitely malignant. His prognosis is excellent for cure.

By this plan we do not submit to operation the cases that respond satisfactorily to medical treatment. If symptoms recur while the patient is still under treatment, then again unless there is some strong contra-indication to operation, the latter should be carried out without delay as the lesion may be malignant and if it is not, some mechanical condition tending to recurrence is usually present.

When operation is undertaken and a gastric ulcer is found, even though there is nothing in its appearance to suggest malignancy, we perform a subtotal gastrectomy just as if the ulcer were known to be malignant. This is done because nothing in the gross appearance of the lesion can with assurance rule out a carcinomatous involvement in what appears to be a benign ulcer. Gastro-enterostomy and local excision of the ulcer are unjustifiable in the patient with a gastric ulcer who is a good surgical risk. If the lesion is malignant, it is almost certain to recur after local removal, while subtotal gastrectomy with meticulous removal of the lymph glands of drainage will cure many of these ulcers that prove microscopically to be malignant. By following this plan, operation is avoided in 50 per cent or more of the patients with chronic gastric ulcer. The results in the benign ulcers that have required operation have been most satisfactory and several carcinomatous ulcers have been resected in a stage in which the prognosis for cure is excellent. We have two patients who had carcinomatous gastric ulcers alive and well

now seven and one-half and eight years, respectively, after gastrectomy and several others for shorter intervals.

SUMMARY

1. The danger of malignancy in gastric ulcer absolutely requires the differentiation of gastric from duodenal ulcer.
2. Many gastric ulcers, some very large ones, will heal under dietary treatment.
3. The progress of healing must be followed by roentgenographic examinations. Symptomatic relief is entirely inadequate as a guide to treatment.
4. Refractoriness to medical treatment is

Fig. 5.

usually due to malignancy or adherence of the ulcer base.

5. A procedure is outlined for the handling of gastric ulcers which attempts to avoid these pitfalls. By it operation is avoided in many cases. Results have been excellent in the benign ulcers that are refractory to medical treatment. And a number of carcinomatous ulcers have been resected with the delay of only a month while the prognosis for cure is good.

ORGANIZATION OF PHYSICIANS, DENTISTS, NURSES, AND PHARMACISTS

A permanent organization of the physicians, dentists, nurses and pharmacists of New Jersey was perfected on September 12, 1934, in the executive offices of The Medical Society of the State of New Jersey.

The need for such an organization was felt during the legislative session of last Winter and Spring when measures of mutual interest to the members of the four groups were under consideration.

OBSTETRICAL PRACTICE IN NORTHEASTERN NEW YORK STATE

EDWIN M. JAMESON, M.D.

Saranac Lake

It is well for business men in any line of endeavor to pause occasionally and take inventory. This survey was undertaken for the purpose of evaluating the type of obstetrical work being done in that portion of New York State which comprises the counties included in the Fourth District Branch of the New York State Medical Society* and of comparing the results with similar surveys made elsewhere in the country. It has not been an easy task and would have been impossible but for the co-operation of the superintendents of the various hospitals who so kindly supplied the necessary data.

This survey is based upon records from the maternity services of twelve hospitals in the district and from data furnished by the district health officers. As nearly as could be determined, about one-third of all births in northeastern New York State take place in hospitals, although the figure varies considerably in the different localities. Four of the hospitals were located in cities of more than 10,000 population and may be considered urban, the remaining eight were located in towns of less than 10,000 population and may be considered rural. There was no appreciable difference in the operative incidence, still-birth or infant death rates in these two groups. The maternal mortality was somewhat higher in the urban hospitals.

The great majority of obstetrical practitioners represented in this group are general practitioners so that the data may be regarded as a cross section of obstetrical practice in the average general hospital in the district. The survey covers a period of five years from 1929 to 1934, and comprises records on 5,914 cases past the sixth month of gestation. In some data the reports are incomplete so that all the figures are not based upon the entire series.

Of the 5,914 cases, 1,636, or 27.6 per cent, were delivered by some operative procedure. This means that nearly one in

every three parturient patients was considered to be in need of some artificial measure to effect delivery. As was to be expected, in a large proportion of these cases (22.8 per cent of the total) forceps were used. About one in every four women had forceps applied.¹ This figure may be compared with that of 17.4 per cent obtained by Plass in a survey of 207 representative general hospitals in the United States with 121,000 deliveries. Plass concludes his paper reporting this survey with the statement: "When the use of forceps is limited to actual need, instrumental delivery is uncommon and probably represents not more than 5 per cent in any given consecutive series. Any great increase over this figure savors of meddling midwifery." From an analysis of numerous large series of forceps deliveries the same author has found that approximately 6 per cent of all babies delivered by forceps will be either still-born or will suffer neonatal death. With low forceps the rate is 3 per cent, with midforceps it is five times higher (about 15 per cent), and with high forceps it is at least 30 per cent.

Other hospital series with which the incidence of forceps deliveries may be compared include the Bronx Hospital with a figure of 6.04 per cent, Novey's series from the University of Maryland with 3.5 per cent, and the Morrisania Hospital in New York City with an incidence of 10 per cent.

Of 1,894 deliveries reported with details on morbidity, 172, or 9.08 per cent, showed a puerperal infection as determined by the American College of Surgeons' standard of 100.4° F on two successive days. This standard is usually considered too lax and most obstetrical specialists have adopted a stricter criterion of morbidity. The only report encountered in the literature which seems to have used this standard was from the Morrisania Hospital (a municipal hospital in which conservatism is emphasized), where a figure of 7.7 per cent was quoted.

The somewhat more rigid standard in use in the Royal Victoria Hospital in Montreal regards a single rise of temperature to 100.5° F at any time during the

*The Fourth District Branch of the New York State Medical Society comprises the following counties: St. Lawrence, Franklin, Essex, Clinton, Fulton, Montgomery, Warren, Schenectady, Washington, Hamilton and Saratoga.

hospital residence (exclusive of the first 24 hours after delivery) as evidence of morbidity. This hospital's figure of about 20 per cent may be compared with that of 14.7 per cent in this series. While this is apparently a favorable comparison, the Royal Victoria Hospital's figure includes abortions and cesarian sections; the series under discussion does not include gestations of less than six months' duration and in many hospitals in the district the cesarian section cases are carried on the surgical services.

DeLee regards a single rise of temperature to 100° F. as indicative of maternal morbidity and finds that in the Chicago Lying-In Hospital (in which both obstetrical and gynecological cases are treated) about 42.5 per cent of the maternity cases fall within the morbid group. Of 1,421 cases in the present series analyzed from this standpoint, 359, or 25 per cent, were morbid. Again the comparison appears to be favorable but the factors mentioned in the preceding paragraph must be taken into consideration and one would expect that the patients covered in the present group, coming as they do from rural or suburban surroundings, would be likely to be of healthier stock than DeLee encounters in Chicago.

Toxemias of pregnancy led the list of causes of maternal morbidity, with infections present on admission (mostly upper respiratory) second, and acute nephritis third. In common with the generally accepted belief, many of the temperature rises occurring on the third or fourth days were regarded as due to the milk. This factor is no longer regarded as a cause of fever by many obstetricians who point out that since it is not exhibited by every woman, it is therefore not physiological. It is also to be recalled that sloughs resulting from tears and infections of birth canal lacerations would be most likely to become manifest about the third day postpartum and would coincide with the so-called "milk fever."

One frequently hears the statement that infections are less likely to occur in home deliveries than in the hospital. This is probably only a partial truth, although there is no doubt that fewer operative deliveries are conducted in the home than in the hospital. At the same time, however, temperatures are not taken as regularly in cases delivered at home and it is highly

probable that many elevations of temperature are unsuspected and remain undiscovered. Goodall found that 80 per cent of cases of puerperal infection were symptom-free and it would seem unlikely that home deliveries should be entirely free from a share of these cases.

Of the 5,914 cases covered in the survey, cesarian sections were done in 135 instances, an incidence of 2.2 per cent. This is somewhat more than double the figure usually given for the United States as a whole and that found by Plass in his Iowa survey. The figure may also be compared with an incidence of 0.6 per cent for the Morrisania Hospital and with figures varying from 0.5 per cent to 3 per cent for various hospitals in Detroit. It should also be compared with Nicholson's report of 90,926 women delivered by midwives in Pennsylvania in which only 4 cases were submitted to cesarian section and in which there were only 77 maternal deaths and an infant mortality in the first four days of life of only 0.02 per cent.

The indications for the use of cesarian section were stated in only 32 instances in the cases collected from the hospitals in the Fourth District (25 of which were from one hospital whose incidence was 4.3 per cent) so that no inferences are possible. It is improbable, however, that an incidence over twice that for the United States as a whole, over three times that of the Morrisania Hospital, and so much greater than that given in other series is based upon recognized justifiable indications.

There were 54 maternal deaths in this series of 5,914 cases—a rate of 9.1 per 1,000. This figure may be compared with that of the Registration Area of the United States in 1929, which was 7 per 1,000; with 2.4 per 1,000 recorded by the Maternity Center Association of New York City in which the cases received adequate prenatal care; with 5.3 per 1,000 for New York City at large; and with 1.8 per 1,000 for the Bronx Hospital. No data are available by which the maternal death rates for hospital and home deliveries may be compared, but it was found that the rate for the four urban hospitals in the district was 9.5 as compared with 8.9 for the smaller hospitals.

Of these 54 deaths, 15, or 28 per cent, were attributed to toxemias of pregnancy, 3 to sepsis, 2 each to placenta praevia, rup-

tured uteri cesarian section, intercurrent acute infections (scarlet fever and pneumonia), 1 each to heart disease, embolism, urinary suppression before admission (not delivered), influenza with infection from a macerated fetus (sic), auto accident, shock, postpartum hemorrhage, tuberculous meningitis, cerebral hemorrhage, and, curiously enough 1 to a contracted pelvis. In 18 instances the cause of death was not stated. Of the 36 in which the cause of death was given it is probable that at least half could have been prevented by proper prenatal care before confinement or proper management of the confinement itself. If these 54 deaths were divided equally among the physicians practicing in the district and distributed over a period of five years so that each lost a mother every two or three years, the weight of responsibility would not be appalling. Yet the total is not in keeping with the ideals of a profession whose duty it is to safeguard human life.

There were 297 still births in the group—an incidence of 50 per 1,000. About 43 per cent of the still-births in the district occurred in the hospitals, although only a third of all the maternity cases were handled in institutions. This figure may be compared with that of 22 per 1,000 for the Bronx Hospital. Figures obtained from the New York State Board of Health show that the still birth rate for Franklin and St. Lawrence counties is 42 per 1,000. This rate for still-births is almost twice that obtained by Plass in Iowa (2.94 per cent), twice that of the Maternity Center Association (2.7 per cent) and almost as high as that of New York City as a whole (4.7 per cent).

If the figures obtained from the seven Boards of Health that reported be combined, the still birth rate in 16,481 births in the district is 41.5 per 1,000. In communities with a population over 10,000, the hospital rate is 53 per 1,000 and in the smaller communities the hospital rate of 48 per 1,000 approaches, but does not attain the figure for the district as a whole. This is an interesting point and is not entirely explained by the high incidence of operative deliveries because the operative incidence for the hospitals in the larger centers is almost exactly that of the smaller communities.

In the cases obtained from the hospitals the cause of the still birth was unknown or not recorded in 204 instances. Of the re-

maining 93 cases, 39 per cent were premature, 20 per cent were attributed to toxemias of pregnancy, and 13 per cent were due to developmental defects in the fetus. Other causes given included cord around the neck, 5, placenta praevia, 5, breech deliveries, 6, birth injuries due to attempts to deliver through contracted pelves, 2, prolapsed cord, 3, maternal infection (no details), 3, and 1 each to prolapsed uterus, diabetic mother, and cesarian section. Not a single instance was attributed to syphilis which is recognized as one of the most common causes of premature deliveries and still-births. Yet in one community where the Board of Health made an attempt to check up on mothers who had given birth to still-born infants, three of the first four examined were found to have a positive Wassermann.

Northern New York has lately been severely censured by the State Department of Health for its high still-birth rate and the situation is indeed intolerable. Analyzing the still-births in the United States Registration Area for 1920 and 1929, Litzenberg found that 64.3 and 55 per cent, respectively, were due to conditions amenable to preventive measures. There is evidence that about the same proportion would be found to hold true in this series. As far as birth injuries as a cause of still-births are concerned, Plass found that still-births occurred four times as frequently in operative as in spontaneous deliveries, and it is recognized that high forceps and version and extraction carry an almost prohibitive risk to the child even in the hands of experts. Among spontaneous deliveries in Iowa, Plass found the still birth rate to be 2 per cent, as compared with 8 per cent for operative deliveries. As he is careful to point out, this association of a high still birth rate with operative deliveries is surely significant and may be partly explained by the obvious fact that complications of pregnancy demanding delivery often of themselves prejudice the child's chances of life. On the other hand, he believes that the relatively high operative incidence for his group (which is less than that found in the series under survey) would indicate that many "convenience" operations were performed and it is generally agreed that they endanger the child's life to a certain extent. In urban hospitals where Plass found an operative incidence of 23.1 per cent, the total still birth rate was 3.9 per cent as

compared with a rural hospital operative incidence of 14 with 2.7 per cent still-births. As has been shown above, there is but little difference between the rates for urban and rural hospitals in the Fourth District (5.3 and 4.8 per cent, respectively), but both are higher than the rate for the district as a whole (4.1 per cent).

The infant mortality rates for Northern New York State have also been under criticism by the State Department of Health and action has already been taken to find the causes and supply a remedy. According to *Health News*, about 80 per cent of the neonatal deaths result from causes pertaining to the function of maternity, congenital malformations, birth injuries, and prematurity. Prematurity alone accounts for two-fifths of them according to this source.

As this survey was primarily concerned with those deaths which occurred from causes pertaining to the maternal function, only those deaths which occurred in hospitals were studied. There were 197 such deaths in the group—an incidence of 33.3 per 1,000. It was impossible to compare the neonatal deaths with those of the district as a whole because neonatal deaths in the vital statistics of the district are taken as those occurring up to the age of one month while in a hospital series the age seldom exceeds two weeks. However this may be, the death rate of 33.3 in this series may be compared with 33 for the Herman Kiefer Hospital of Detroit, which is a city hospital; with 13 for the Bronx Hospital; and with a total of only 29 for the entire first month of life in cases cared for prenatally by the Maternity Center Association in New York as contrasted with a figure of 43 for a control group in New York City. It may be noted in passing that the figure given by the District Health Officers for the Fourth District is 44.2 per 1,000, which is higher than that of New York City in spite of the fact that the counties covered in this survey are essentially rural and would be expected to have a much lower rate.

Of the 197 neonatal deaths that occurred in the 12 hospitals during the five years covered by the survey, 81 were reported in sufficient detail to analyze. Forty-four (54.3 per cent) were due to prematurity. No doubt this figure has obtained for years, yet there are only two or three hospitals in the district which have an infant incubator

and facilities for caring for premature babies. Thirteen, or 16 per cent, were ascribed to birth injuries. It is probable that many of these might have been prevented. Other causes of death included congenital defects, 9; icterus neonatorum, 1; "weak babies," 2; cesarian section, 1; twin birth, 3; atelectasis, 1; unknown, 8.

If the still-births be added to these neonatal deaths, one gets the appalling total of 494 dead babies in 5,914 deliveries. In other words, there will be one infant death in every 12 babies born in northeastern New York State.

COMMENT

It would seem superfluous to attempt to add anything by way of comment to the evidence brought forth by this survey. Present conditions of obstetrical practice in northern New York are disgraceful and intolerable. Nor are signs of improvement evident. While it is true that some of the factors responsible for this poor showing are outside the physician's province, there is still much that he can do. Dr. Parran has pointed out that the level of medical practice in a community can be no higher than the intelligence of the people who make up that community and some of the conditions revealed by this survey can be corrected only by regarding them as public health problems to be solved through the medium of a state-wide educational program. Women must be educated to the value of prenatal care and physicians can refuse to accept cases who have not applied for such care before labor begins. On the other hand, there is no doubt that many physicians have neglected their responsibilities to the patient who has consulted them during the prenatal period and the management of the confinement itself has not always been rational. Prenatal clinics as conducted by the State Board of Health or other outside agencies are not satisfactory—at least in Saranac Lake there was no appreciable improvement in the figures during the two or three years such a clinic was maintained. Prenatal care to be efficacious must be in the hands of the physician who is going to handle the confinement as it is only by observation over a long period of time that he can "size up" his patient and plan her delivery along safe and sane lines. As for the confinement itself, more obstetrics and less meddlesome midwifery is needed. The difference

between the two has been admirably outlined by DeLee in a paper that should be studied by every physician who undertakes to practice obstetrics. It is perhaps a sign of the times that the program of so many county and district medical society meetings includes a paper on "The Use of Forceps." The need is for greater emphasis on the management of normal labors and it is gratifying to see occasionally a program such as that of a recent clinical convention in which the head of the department of obstetrics and gynecology of the

medical school at which the convention was held chose for his subject "Normal Delivery."

CASE REPORT

CONGENITAL FUSION OF ASTRAGALUS AND SCAPHOID BILATERAL, INHERITED

ABRAHAM S. ROTHBERG, M.D. JOEL W. FLIDMAN, M.D.
and OTTO F. SCHUIFLER

New York City

Congenital abnormalities are often seen, incidentally, when examining for other conditions. For example, bi-partate sesamoids, fusion of metatarsals and cuneiform, cuneiform and cuboid, and the usual commoner variations from the normal are found when roentgenograms are studied for suspected fractures, and so on.

There are some cases mentioned¹ in the literature of fusion of the astragalus and scaphoid, but these are due to infections, arthritis or surgery, and are not congenital.

Although various fusions are found, the congenital astragalo-scaphoid variety is extremely rare. Pfitzner² and Dwight³ who wrote extensively on variations of the bones of the feet never saw a case of congenital fusion of these bones.

Anderson⁴ reported the autopsy of a man of thirty four years of age, without any available history, in whom were found bilateral astragalo scaphoid fusions probably congenital.

Holland⁵ reported a case of a woman twenty one years old, with bilateral and symmetrical fusions of the astragalo-scaphoid and calcaneo cuboid joints, also the second and third metatarsals were fused to their respective cuneiform bones. The carpal bones also had some bilateral anomalies. These were roentgenogram findings

These were presumably of congenital origin.

Illievitz⁶ reported a case of a boy of seventeen, who had four toes, four metatarsals, and a congenital fusion of the astragalus and scaphoid, all on the right foot. The left foot presented no clinical nor x-ray variations.

Bullitt⁷ reported a case that he discovered in routine x-ray examination for a sprain in a man of thirty-five. There were definite bilateral congenital fusions of the astragalo scaphoid joints. Incidentally, there were large accessory scaphoids. He quoted Dr. Meyer as to criteria in determining the congenital from the acquired fusions.

The trabeculae of the spongiosa in the talus [in the congenital fusions] are continuous to the anterior surface. In cases of ankylosis, there would be a line of demarcation unless it occurred early in life and were of long standing.

Lapidus⁸ describes the case of a girl of nine with congenital fusion of the astragalo scaphoid joints of both feet. X-ray examinations of both parents and the brother of the patient did not reveal any abnormalities.

One of the authors⁹ described a case of a man of thirty five in whom was found excessive mobility of the right scaphoid-

Fig. 1.

Fig. 2.

cuneiform joint, clinically. X-ray of the right foot revealed a congenital fusion of the scaphoid and astragalus of the right foot, and no abnormality of the left.

Our case is that of a girl, eight years old, who presented herself because of pains in the calves of the legs and tired feeling in the lower extremities. About two years previous to her admission to the clinic, her mother noticed a knobby prominence at the inner side of the feet. There was no particular pain at this site. Patient had no accidents, no arthritis, nor any disease involving the bones of the feet.

Examination revealed a well-developed child, with mild weak feet, with a slight protrusion at the heads of the scaphoids. The contour and shape of the feet were otherwise normal. There was no limitation of motion of the feet; no spasm nor rigidity. Pulses were good. Local and general neurological examinations were negative. Posture was good. Whitman cupped heel-plates were prescribed and worn with relief of symptoms, but the prominence did not recede.

X-rays were advised expecting to find accessory scaphoids (tibial externum). These revealed marked enlargement of the neck of the astragalus and the scaphoid fused to it. No other abnormalities were

Fig. 3.

observed. (See Fig. 1 and Fig. 2). X-rays of the hands did not show any deviation from the normal. (See Fig. 3.)

X-rays were then advised for all the

Fig 4

Fig 5

members of the family. The brother, age eleven, has never had any foot trouble, but has similar prominences over the heads of the scaphoids. The X-ray plate is similar to that of his sister (See Fig 4)

The mother, age thirty-one, does not remember any prominences at the inner side of her feet at any time. She has never had any symptoms referable to the feet. She does not recall having seen any bony prominences at the feet of any of her brothers or sisters, father or mother. The shape and contour of the feet are normal. X-rays of her feet show abnormalities similar to those found in her son and daughter (See Fig 5)

SUMMARY

1 Of all the congenital fusions of the feet, that of the astragalo scaphoid is the rarest

2 Three cases of bilateral congenital fusion per se were culled from the literature. One case of unilateral fusion per se was also described

3 A case of bilateral congenital fusion of the astragalo-scapoid joint is reported. The same X-ray findings were observed in the girl, her brother, and then mother

4 This is the first and only case of bilateral congenital fusion of the astragalo-

scaphoid joint on record with definite hereditary factors

ACKNOWLEDGMENT

Patient and material are from the Foot Clinics of New York

We wish to express our thanks to M F Petti, Ringel, and Silver, of the X-ray Department for their help and co operation

"Elementary Rights of Children" and the Proposed Child-Labor Amendment

The fight is now on, it appears, as legislatures meet, over ratification of the proposed child-labor amendment to the U. S. Constitution. It is an opportune time, then, for this JOURNAL to repeat flatly and emphatically, that it is opposed to ratification, and to state why. The "elementary rights of children" are involved, says Mr. Courtenay Dinwiddie, secretary of the National Child Labor Committee, in a letter to a member of our Management Committee, seeking to persuade us to alter our stand. And Mr. William Green, president of the American Federation of Labor, is out with an appeal to labor organizations to work for ratification.

It is certainly not necessary to say that the physicians who brought these children into the world, and have watched unremittingly over their health and welfare, desire now to save them from the evils of child-labor. No one has a better right to the title of their friend and protector. But the physician demands that measures for their protection be founded in wisdom, not in emotionalism. The physician believes

that the task of protecting the children should be left to the sovereign states and not to the Federal Constitution, where it is totally out of place. This stand of our State Medical Society was fully explained in our issue of April 1, and the seeming paradox of physicians eager to protect children from damage by overwork, and yet antagonistic to the amendment, was made clear.

We are entirely at one with the friends of the amendment in opposing improper work in childhood. We accept without question, proof that conditions over the country before the present codes came into being were unsatisfactory, and we do not doubt that some of the opposition to the amendment comes from those who put cash before humanity. Nevertheless, we reaffirm with conviction and without hesitation our belief that the amendment would invade the "elementary rights of children" at a deeper level than in the worst days of exploitation.

The truth is that there is no place in the constitution for such an amendment. It would work a greater harm than the evil it seeks to prevent. It would be misgovernment. It reads:

"Section 1. The Congress shall have the power to limit, regulate and prohibit the labor of persons under eighteen years of age.

"Section 2. The power of the several states is unimpaired by this article, except that the operation of state laws shall be suspended to the extent necessary to give effect to legislation enacted by the Congress."

To give to Congress "the power to limit, regulate and prohibit the labor" of 45,000,000 persons under 18 years of age is a mistake. In the American system the parents are charged with control of the children, under State laws which enforce proper schooling and care. When parents fail or die, children become the wards of the State. They never become wards of Congress and never should, unless indeed it be desired to abandon the principle of local government in favor of Sovietizing the land. Child supervision should not be given to Congress.

We do not believe that the proponents have any motives except a sincere desire to promote the young from brutal, harmful,

overlong work to the detriment of health, mental and physical development and education. We do believe, however, that, in their eagerness to do good they have paid too little attention to the fundamental features we have stated and to the possibilities for unwise Congressional control which are inherent in the amendment.

It is unfortunate we think, that the medical profession was not consulted ten years ago when the amendment was first promulgated. Its official organizations should have contributed not merely first hand data from practicing physicians of damages inflicted by what is called child labor, but could also have painted a picture of all the "elementary rights of children" which should be preserved. It could have shown the need for happy homes where children have time to play, time to learn from books and life, but where they also prepare, by study and emulation of adults, for manhood and womanhood. In particular, it could have stressed the value of steadily increasing responsibilities within capacity, in *work* of any kind, real work, just enough and not too much the "elementary right" to develop true mental, moral and physical strength through real experience.

To take control from the parents under the State laws would be to deprive the child of his deepest right—the right to grow up under the best supervision that American life can supply.

We repeat the JOURNAL believes in State laws to protect children. It further is of the opinion that in framing those laws the State governments should seek the aid and advice of organized medicine.

Better Team Work for Nurse and Doctor

Few are more competent to advise us on this important subject than Dr. Donald B. Armstrong of the Metropolitan Life Insurance Company, a member of the State Medical Society who has had a wide contact with nursing problems during his extended and useful career in health work. In theory as well as in practice the physician and the nurse constitute a team that

can work well only with understanding on both sides of the partnership. He told an audience interested in nursing a few weeks ago at White Plains. He was speaking more especially of the private medical practitioner, the general family physician, in his relationship to public health nursing organizations.

The "primary job" of the nurse, he frankly told his audience "is the supporting and upholding of the private family physician." The nurse is interested in preventive medicine and, if she will, she can help to promote the use of the private practitioner's preventive medical services and so not only improve her relationships with the doctor, but aid in opening up an important field of medicine. She can as she goes here and there, advocate health examinations, encourage early diagnosis of incipient disease, promote immunizations, recommend prenatal medical service, pre-school examinations, correction of defects, and so on.

Then, too, the nurse can guard against certain tendencies that may antagonize the physician and cause discord instead of harmony. These tendencies are contrary to both medical ethics and nursing ethics, and we may hope that they have disappeared entirely now, but they have been known to occur in the past and should be rigidly guarded against in the future. Dr. Armstrong mentioned among these such simple errors as the making of diagnosis, the prescribing and administration of therapeutic measures beyond the medically approved standing orders, contradicting medical advice, playing medical favorites, referring patients to specific physicians, and recommending a change of physicians. Nurses are often strongly tempted to make some of these errors but should realize that both medicine and nursing are best served by sticking to strict ethical practice.

The doctor for his part we are told does not appreciate how much the public health nurse can do for him. At least that has been Dr. Armstrong's observation—"he knows the nurse, but not the public health nurse." Dr. Armstrong relates that his company has been trying, in several large cities, to cut pneumonia mortality by

increasing nursing care. "We have approached the physicians," he says, "and urged them to call for the nurse. We have even agreed to share visiting nurse associations' costs, should these calls become excessive. Thus far little progress has been made," he adds with considerable heat and feeling, "primarily because the rank and file of physicians in our larger cities, with excellent nursing organizations, are scarcely aware of the existence of the nurses, don't know what they do or what they are supposed to do, do not know how to call them, and have an attitude toward them based on ignorance, or suspicion and distrust."

No doubt the doctors could say something on their side of this question, but whatever the cause, Dr. Armstrong urges the nursing organizations to "sell" their services to the doctors and convince them of their helpfulness. They should wipe out any existing causes of irritation and conflict. If the doctors are not calling in the co-operation of the nursing organizations, then it is safe to say that there are perfectly sound reasons for it, and the duty of the nursing organizations is to find what these reasons are and remedy them.

We Have Them Worried

The cocksure attitude of the managerial reformers who aim to regiment the medical profession seems to be wavering. Miss Frances Perkins, Secretary of Labor, and one of the chief backers of the scheme, now admits that there are "many difficulties in the way of health insurance, including the attitude of much of the medical profession." The President himself speaks of it as something that may come "soon or later on," which looks like putting it on the shelf for the present.

There has fallen into our hands a copy of a letter sent around by John B. Andrews, secretary of the American Association for Labor Legislation, to those who "favor early action looking toward the adoption of suitable health insurance legislation." The list of officers and "General Advisory Council" on the letter head reads like a Who's Who of the "general

advisers" of the nation who make it their business to tell everybody what to do. The letter is rather hysterically marked "Urgent" and declares that if the recipient favors health insurance "it is very important that you so wire or write to the President, at the White House, or to Miss Francis Perkins, Secretary of Labor, Washington, D. C., *at once*."

Here we have evidence that all is not going so smoothly as expected with the plan to "sovietize" American medicine. The doctors have had the temerity to speak up for themselves, and it is plain that many of them are doing so. Free speech is a cornerstone of our liberties, and the future liberty of the physician certainly rests upon his speaking freely, and forcibly, right now. If the friends of medical regimentation find it "urgent" to wire or write the President "at once," then it is just as urgent for the doctors to wire or write and express their opposition. The President has a right to hear both sides, and the side of the general practitioner is just as important as the side of these self-appointed "general advisers."

It is not unlikely that the busy physician, suddenly called upon to argue against state medicine, may not have all the points on the tip of his tongue, and may feel hesitant to approach his Congressman or Senator. For his benefit, and to refresh the memory of others, it may be useful to run over the chief points against the plan.

In the first place, our American medical service is, in many ways, adequate just as it is. We have more physicians per capita than any other land, and they give millions of dollars worth of free service to all who need. The quality is high, the rates of death and disease are falling and many diseases are being conquered. The national cost of medical service is less than the cost of many luxuries which the social reformers do not seem to worry about. In fact, we have more medical, hospital, and nursing service than the public calls for, and all health needs can be amply met by the present system without any reorganization.

Then, too, regimentation of the profession would inevitably break the fine per-

sonal relation between doctor and patient, politics would bring in an era of favoritism and perhaps of jobbery, graft, and racketeering, the doctor would lose his independence and be subject to the orders of lay managers and clerks, and the quality of the service would deteriorate.

Reports from foreign countries having health insurance systems say that the quality of service has not been bettered, the death rate has not fallen, and the sickness rate has increased—three times in Germany, two-fold in England. In Germany the insurance doctors are overwhelmed by patients who do not need attention, but wish to be "written sick" to escape work

and draw compensation. Moral deterioration results. Our experience here with workmen's compensation gives a hint of the evils that would creep in under health insurance.

Finally, if some form of mutual group practice is desired, why not let the doctors themselves devise plans which they know from their experience will meet the situation best? They have amply proved their wisdom and devotion to the public good, and are competent to perfect a system that will incorporate all that is desirable and avoid the evils and pitfalls in the ill-considered schemes of shallow enthusiasts.

A NEW SCRUTINY OF THE MEDICAL SCHOOLS

The medical schools are about to have another examination, to see if a weeding out or perhaps an elevation of standards is necessary. The number of students has grown to the point where some think we have an overproduction of doctors. Ten years ago, according to Dr. Thomas Ordway, of the Albany Medical College, the total number of students in the American medical schools was 17,728. In 1933 it increased to 22,799. The total number of graduates ten years ago was 3,562, last year, 5,038. In other words the total number of students in the schools increased 28 per cent in ten years, the total admissions 25 per cent and the total number of graduates 41 per cent.

Dr. William Pepper, of the University of Pennsylvania, notes that Washington is paying farmers for not raising so many hogs, and wonders if the government would not pay his medical college for not turning out so many doctors!

These remarks were evoked by an address by Dr. Ray Lyman Wilbur of Stanford University, Chairman of the Council on Medical Education and Hospitals of the A.M.A. Dr. Wilbur reviewed the radical shake up of the medical colleges a few years ago, and said that a new scrutiny has now become necessary. He said, among other things: "There has been a definite weakening in the fibre of certain of our institutions. A reinspection and study of them will be somewhat painful but it is absolutely necessary in order that no American boy or girl who proposes to go through the long struggle of studying medicine will be misled into putting his or her time in an inferior institution. We have become somewhat too complacent. Institutions recognized by the Council on Medical Education and Hospitals as belonging to the 'A' group have sometimes relaxed after they have achieved such classification. In a number of instances there has been serious debate in the Council on Medical Education as to whether this 'A' rating should or should not be withdrawn."

"We have been judging the medical institutions of this country by their physical plants, their budgets, the preparation of their teachers,

their hospital relationships, and many other factors. The real test is the quality of the graduate and whether he can fit into the active life of the profession and hold up his end of the work to be done."

"Of late we are beginning to discover a slowing down in some of our various medical schools. We can hardly speak of what we note as 'signs of senility.' They seem to be more the results of bad habits and unfortunate procedures than of age itself. In general, our difficulty is an overdose of self-satisfaction, together with too much complacency as to the future."

"This study of our schools should be complete, thorough and accurate, but it should weigh all elements and see each school in its own setting. Comparisons may be quite unfair. Results count."

Above all the situation demands that the study and analysis made be in harmony with the needs of the physician ten years ahead. We must try to pre-empt what he will be expected to do and should do, and plan our medical teaching to prepare him for it."

Research fellowships for the study of pharmacology, physiology, effect of sedative drugs on the horse and ox, alkaloids and bacteriology have been established by Merck & Co. at the Universities of California, Pennsylvania and Virginia.

A study of dermatitis attributed to socks has been made by Dr. Louis Schwartz, Senior Surgeon of the U. S. Public Health Service, who concludes that:

1. Careful investigations should be made in each case of dermatitis due to contact with dyed material to determine whether the material, the dye, or the finish is the actual irritant.
2. Allergic individuals should thoroughly wash the finish and the excess dye off new socks before wearing them.
3. A minimum amount of finishes should be used on socks by manufacturers, and these finishes should be as nearly neutral in reaction as possible.

News

of Interest to the Profession

LABORATORY AIDS IN THE DIAGNOSIS OF BACILLARY DYSENTERY

Bacillary dysentery, like plague, cholera, and influenza, has been one of the great scourges of the world. Although improved sanitation has now greatly reduced its frequency, the disease still appears sporadically or breaks out in mild epidemic form.

The occurrence of a group of cases with sudden onset of diarrhea with blood and mucus in the stools, should prompt the physician to obtain immediate laboratory aid in determining whether or not the epidemic is caused by dysentery bacilli. By such action an outbreak may sometimes be discovered early, the source recognized and eliminated, and the progress of the epidemic stopped. Frequently, however, the etiological agent is not identified, either because no stool specimens are taken for laboratory examination or because they are not taken sufficiently early. Furthermore it is important to remember that single or isolated cases of the disease may occur. In such instances, early laboratory examination of stool specimens may make possible an immediate diagnosis.

The incitants of bacillary dysentery have been found to be a number of different strains of dysentery bacilli which differ from each other more or less markedly. The severity of the infection usually varies, depending upon the particular strain involved. The most virulent form occurs very rarely in New York State.

When dysentery is suspected, the physician is required by state regulation to submit for examination to a laboratory approved for the purpose: (1) A specimen of feces; (2) ten c.c. of blood. Specimens of the feces must also be submitted before the patient is released.

LABORATORY AIDS IN DIAGNOSIS

I. Stool Cultures. It is usually possible to demonstrate dysentery bacilli in the stools at the onset of the illness. The chances of a positive culture decrease rapidly as time elapses. Specimens consisting of bloody mucus are the most favorable for examination. If specimens cannot be delivered immediately to the local approved laboratory, preservative is necessary and special containers provided with suitable preservative may be obtained from the local laboratory supply stations. Cultural examination of later specimens will sometimes yield positive results when the first specimen does not.

II. The Agglutination Reaction. Agglutination tests are of very little assistance as an aid in the diagnosis of bacillary dysentery. Serum from healthy individuals often agglutinates in a high dilution micro-organisms of the Flexner type which the serum from many cases of the other types does not agglutinate the incitant, at least during the early stages of the illness, in a sufficiently high dilution to aid in the diagnosis. However, specimens of the blood for agglutination tests should always be submitted for examination for evidence of typhoid and paratyphoid fevers.

III. Blood Cultures. Dysentery bacilli are rarely present in the bloodstream. Hence, blood cultures are of no help except in so far as they may aid in the exclusion of other types of infection.

Polyvalent antidysentery serum may be obtained from the Division of Laboratories and Research in Albany. Prompt administration of the serum is indicated in severe cases.—(New York State Association of Public Health Laboratories, October, 1934.)

THE ADVANCE OF SOVIETIZED MEDICINE

What has already been done to "sovietize" medicine in this country (to use an original term), Dr. R. G. Leland, Director of the Bureau of Medical Economics of the A.M.A., described recently in an address before the Iowa State Medical Society. After mentioning the lay-controlled schemes and the "fifty or more group hospitalization plans," he continued with a summary of the plans operating under medical control.

Dr. Leland's references to developments in New York State are especially interesting. He said, in part:

Already there is a tendency towards sickness insurance in certain sections of these United States. The entire State of Washington has been organized into what they call medical service bureaus which are essentially sickness insurance organizations giving medical service to certain sections of the population, mainly individual groups of a certain income level. In the State of Oregon there has been, for many years, a law which provides for the certification and registration of hospital associations, which are misnomers but are essentially the same as the medical service bureaus in Washington.

In California a committee of the State Legis-

lature and a committee of the California Medical Association has been working for the last year and one-half to determine the necessity for sickness insurance in that State. It is presumed that at the next session of the Legislature, which meets in January, 1935, a sickness insurance act for California will be presented for passage or consideration, Michigan has already made a very extensive study, and a committee of the state society has presented for the consideration of the House of Delegates a plan of sickness insurance for that state. This plan has not been accepted yet, but if it is accepted, that plan of sickness insurance will be placed in operation in two or three counties in Michigan.

More insidious and more dangerous to the future of medicine is a proposal that comes from New York, sponsored and presented by one of the great foundations of the country, the Milbank Foundation. This proposal comes as a plan to socialize or sovietize medicine in New York. If successful there, it would be an easy and logical development to proceed westward, and no one can predict how fast or extensive it would proceed.

All of these attempts to mechanize, to socialize, or to sovietize medicine are perhaps the strongest of the disturbing elements to physicians today. It is hard to tell just exactly what might happen were such an event to occur in these United States; but I can state truthfully that I see some comfort in the fact that I believe the American people desire their own physicians. They do not want the kind of medicine that is dealt out mechanically.

Unfortunately, all of these disturbing influences are not outside the medical profession. I have suspected for some time, and I now have some evidence, that there are a few within the medical profession who would sell out the medical profession for a mess of pottage. There is a group of physicians, about 500 in number, who constitute the League for Socialized Medicine in Brooklyn. There are physicians here and there, a few, who would sell out their own societies for a certain consideration. We must watch for these people. The promotion of socialization schemes is being furthered by the action and the attitude of some of these physicians.

SURGERY USED TO DEFEAT JUSTICE

Plastic surgery to change the faces of criminals and skin-grafting to hide their finger prints, are devices that must now be reckoned with by our agents of justice. "If we can char . . . have changed the . . ." says Dr. Howard . . . *American Journal of Surgery*. In other words, one disguised print would send the sleuths of the fingerprint bureau off on a false scent in a wrong section of the card-index.

Some of the tricks are vain, however. Thus skin grafts taken from one person and transplanted to another, or taken from animals, are seldom successful. Ordinary skin, too, taken from other parts of the body, with the exception of the palms of the hands and the soles of the feet, does not contain the characteristic ridges and will not develop them on transplantation. But certain areas of the palm and sole contain such characteristic ridges as are found on the finger tips, though not of the same group.

Dr. Updegraff reports a case in California

where the surgeon was reconstructing the burned hands of a patient. He covered the tip of the right forefinger with a skin graft from the palm, with similar skin ridge markings. In such a graft the ridges do not appear completely for several months, and even then the edge-scar of the patch and the scar where the patch was taken would betray the subterfuge. But if this sort of surgery is perfected, then what becomes of all our fingerprint system of detection? Besides, emphasizes Dr. Updegraff, if fingerprint classification is not to mean identification, we must realize that the criminal who is smart enough to have his fingerprints altered is going to have other surgical aid. Plastic surgery is being utilized to defeat justice by changing facial contours, removing scars, and so on.

When we have a national act requiring universal identification measures we must have not only fingerprints, but prints of the palms and soles as well. Added to this must be an up-to-date understanding of plastic surgery possibilities.

MEDICAL BROADCASTS

Scheduled under the auspices of the Medical Information Bureau of the New York Academy of Medicine and the Medical Society of the County of New York from Station WABC, Columbia Broadcasting System:

Thursday, January 3, 1935, at 11:15 A.M., 15 minutes.

Subject: "New Year's Resolutions."

Speaker: Dr. Smiley Blanton, Assistant Professor of Psychiatry, Cornell University Medical College.

Thursday, January 10, at 11:15 A.M., 15 minutes.

Subject: "Pneumonia."

Speaker: Dr. Jesse M. Bullowa, Clinical Professor of Medicine, N. Y. University Medical College.

Thursday, January 17, at 11:15 A.M., 15 minutes.

Subject: "Burns and Their Treatment."

Speaker: Dr. Fenwick Beekman, Attending Surgeon, Bellevue Hospital.

Thursday, January 24, at 11:15 A.M., 15 minutes.

Subject: "Oxygen and Pneumonia."

Speaker: Dr. Jesse M. Bullowa, Clinical Professor of Medicine, N. Y. University Medical College.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Illegal Practice of Medicine—A Quack is Convicted of Manslaughter

A glaring example of quackery is set forth in a case* which came before the courts of one of the Southwestern States a few years ago. A fake medical practitioner was convicted on a charge of homicide. A review of the facts in the case illustrates anew the menace to the public health of quacks of this character.

A certain "T. L." was suffering from a severe attack of grippe which was bordering on pneumonia. He had been ill for some time, and was slowly improving under the care of a competent physician. His temperature had been as high as 104, his pulse between 90 and 100, and his respiration above 30. His temperature was 100, pulse 85, and respiration 24 on the morning that the regular physician last saw him. On that day a certain "J. B." was brought in to attend the patient. This man was not licensed to practice medicine but despite that fact set about treating the patient according to his own ideas.

The first and apparently the principal step in the treatment was to brew a sort of tea made by parching and boiling hog hoofs that had been long thrown out as waste and refuse, and which had apparently become very filthy and putrid. He then administered considerable amounts of the concoction to the sick man, explaining to him and to his family, that the brew possessed remarkable curative qualities which would alleviate and cure the patient of the ailments from which he suffered. Part of the treatment administered by "J. B." consisted of his rubbing the limbs and body of the patient, and at the same time making a prayer or incantation. This quack also gave the patient a heavy dosage of some drug as a headache or fever powder. The treatment, so described, was continued for two days and the patient died.

The fake practitioner was shortly thereafter indicted for manslaughter in the second degree under a statute reading:

Any killing of one human being by the act, procurement or culpable negligence of another,

which, under the provisions of this chapter is not murder, nor manslaughter in the first degree, nor excusable nor justifiable homicide, is manslaughter in the second degree.

The case was tried and the defendant was found guilty of the charges and was sentenced to a two-year term of imprisonment in the penitentiary. From that judgment an appeal was taken to the highest court of the State, which affirmed the said judgment.

One of the principal contentions which the accused urged upon the appeal was that the evidence failed to establish that the death of "T. L." was caused by his culpable negligence. There was evidence in the record of the trial to the effect that in cases of illnesses such as the one in question, even with the exercise of the best of medical care and skill, there is a considerable death rate. According to certain testimony introduced upon the trial that mortality rate ran from 10 to 40 per cent of the cases. The appellant claimed that because of the said testimony the evidence of guilt amounted only to a suspicion, and the crime was therefore not proved with the degree of certainty required to convict in a criminal cause. The Appellate Court, however, adopted the view that the acts of the defendant were unquestionably one of the direct causes of the patient's death, and that the so-called cures were detrimental to the patient's life. In so ruling the Court said in part:

The treatment given the deceased by the defendant was not indicated for the disease from which the deceased was suffering; it in no way tended to alleviate the suffering or had any curative properties whatever. On the contrary, the treatment administered, considering the time it was given, was evidently detrimental to the patient's health. Defendant possessed no knowledge of the curative properties of medicine, was not licensed to practice medicine in the State, and was grossly ignorant of the manner in which the disease from which the deceased was suffering should be treated. The application of hands, accompanied with an incantation of prayer that the pain be transmitted from the body of the deceased to that of the defendant, the administering of hog-hoof tea and of the headache or fever powder at the time it was given, evidenced gross

* Barrow v. State, 188 Pac. 351.

ignorance and culpable negligence on the part of the defendant in the treatment of the disease.

The Court further said in its opinion:

The question here is not whether the deceased would have lived had he received treatment according to the care and skill usual among good practitioners of any recognized and authorized school, but did the treatment given and applied by the defendant contribute to and result in the death of the deceased, and was the defendant grossly ignorant of the manner in which such disease should be treated and culpably negligent of the patient in giving the treatment?

The crime here did not consist in the omission to perform some duty specifically imposed by law. Defendant owed deceased no duty; but having assumed to treat him for disease, defendant was bound to know the nature of the remedies he prescribed, and the treatment he adopted, and he is responsible criminally for a death resulting from gross ignorance and culpable negligence in such relation.

There is no question but that the ruling of the Court was correct. The defendant was a quack of the worst kind. He took over a difficult medical case and substituted his fake cures for sound medical practices. Everything he did was definitely detrimental to the patient's health. His conduct justly merited his conviction.

Plastic Operation on Nose

A man 28 years of age called to the attention of a general practitioner a scar on the side of his nose which he said had been caused by a stabbed bone some years before. The scar was about an inch and a half long with a well-outlined cicatrix. The doctor arranged with the patient to perform an operation for the purpose of trying to remove the scar and to improve the man's appearance. He put him under local anesthesia and made two straight-line incisions on each side of the scar and removed the scar. He then sutured together the skin and applied bandages. In ten days the sutures were removed and two days later it was necessary to treat a small infected blackhead at the side of one of the sutures. The patient came back for examination from time to time for about a month and the result seemed to be a decided improvement, the scar being considerably smaller than before the operation.

Plaintiff brought an action against the doctor in which he claimed that the doctor had so negligently operated upon the nose that the same was caused to be scarred and disfigured to a greater extent than before the operation. The case came on for trial and the plaintiff claimed that he had con-

sulted the defendant about the scar merely because it itched and that the operation was undertaken because the defendant had persuaded him against his will to consent to the operation. At the close of a two-day trial the issues in the case were submitted to the jury with verdict for defendant.

Alleged Negligent Removal of Tonsils and Adenoids

The defendant in this case was engaged to remove the tonsils and adenoids of the plaintiff, an infant of thirteen years of age.

The boy entered a hospital where the doctor performed the operation, removing his tonsils and adenoids. The boy was discharged from the hospital the day following.

A suit was instituted against the doctor alleging that he negligently performed the operation for the removal of the tonsils and adenoids and that as a result of such negligence the boy suffered a paralysis of the glands and muscles of the throat, head, and arms.

Upon investigation it was learned that this infant at one time had had an attack of spinal meningitis. Further investigation revealed that the infant also was suffering from a progressive spasmodic torticollis.

In the opinion of the physician who had made a physical examination of this infant subsequent to the operation, and who had also seen him over two years prior to the operation, the condition this infant plaintiff was suffering from was not dependent upon, nor in any way connected with the operation performed by the defendant.

It was brought to light that prior to the operation performed by the defendant an application for insurance on the life of this infant had been made by his parents and that the insurance company had refused to issue its policy because of this boy's physical condition.

This case which was instituted by the boy's mother (who had been appointed guardian *ad litem* for the purpose of instituting this case) was placed on the calendar for trial. The attorney for the plaintiff made various requests for adjournments and finally the case was marked off the calendar. Over three years elapsed and no steps were taken by the attorney for the infant plaintiff to prosecute this action. Thereafter, on motion of the defendant doctor, the action was dismissed for lack of prosecution and an order and judgment entered disposing of the matter.

Books

BOOKS REVIEWED

A Practical Treatise on Diseases of the Skin for the Use of Students and Practitioners.—By Oliver S. Ormsby, M.D. Fourth Edition. Octavo of 1288 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$11.50.

This fourth edition of Ormsby's book has been so completely revised and rewritten that it might well be considered a new work in dermatology. As such it is probably the most complete and practical book on this subject in the market to-day; and it has the added attraction of coming from a man with wide clinical and teaching experience, as well as real literary ability. His descriptions of the various dermatoses are written with the greatest clarity, and seem to more definitely conjure up the picture of the disease than any we have read.

The reviewer heartily recommends this book, knowing that it is a necessary part of any medical library.

E. ALMORE GAUVAIN

Physical Treatment by Movement, Manipulation and Massage.—Being the Third Edition of *Massage, Its Principles and Practice*. By James B. Mennell, M.D. Octavo of 618 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1934. Cloth, \$6.00.

The first seven chapters of the latest revision of this instructive work describe massage, beginning with its physiology, general principles, various methods, and finally technic in detail.

Every type of apparatus is described that will restore diseased or injured parts to their normal functions.

The treatment of recent injuries, such as sprains, dislocations, and fractures includes immobilization methods, reeducation, massage, and physiotherapy.

The remaining chapters deal with the treatment of deformities and massage as used in internal medicine, neurology and postoperative care. This work makes very interesting reading and a handy guide for the prescribing of massage and manipulation.

JOSEPH I. NEVINS

Urinary Analysis and Diagnosis.—By Microscopical and Chemical Examination. By Louis Heitzmann, M.D. Sixth Edition. Octavo of 385 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$5.00.

The sixth edition of this work has been thoroughly revised. In Part 1, dealing with the chemical examination of the urine, there are some new tests but the author, as heretofore, describes only those tests which the physician can perform himself. Part 2, dealing with the microscopic examination of urine stresses the identification of epithelium from different parts of the genito-urinary tract. The author's studies in this field are so well known as to need no comment. In Part 3, he discusses the diagnosis of genito-urinary diseases chiefly by means of the microscopic examination of the urine.

Dr. Walter C. Dannreuther contributes a chapter on tests for determining the functional efficiency of the kidneys. He describes a number of practical tests.

The last chapter deals with the new hormone tests for pregnancy.

E. B. SMITH

The Principles of Gynecology.—A Text-Book for Students and Practitioners. By William Blair-Bell, M.D. Fourth Edition. Octavo of 848 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$10.00.

The fourth edition of this excellent book has been revised and largely rewritten with the assistance of M. M. Datnow, of Liverpool, and Arthur C. H. Bell, of London.

Since the previous edition was published, much that is new has developed in regard to internal secretions, ovarian neoplasms, and to the nature and treatment of malignant disease. The portions relating to these subjects have been entirely rewritten. New sections

and more than one hundred illustrations, including many colored plates have been added.

In addition to the subjects usually covered in textbooks on this subject, the author has included an excellent section devoted to operative gynecology.

The new edition is a very comprehensive and thoroughly up-to-date textbook.

W. S. SMITH

Applied Physiology.—By Samson Wright, M.D. Fifth Edition. Octavo of 604 pages, illustrated. New York, Oxford University Press, 1934. Cloth, \$5.50.

Careful revision throughout is apparent in this fifth edition, bringing its text into accord with results of research published since 1931. While the general plan of its contents remains largely the same as in the Fourth edition, many of its sub-topics have been rewritten and a number of paragraphs shifted so as to bring into more intimate relationship data bearing upon certain problems which, in previous editions, have been dealt with fractionally under separate headings.

Dealing, as it does, with the facts and concepts of animal physiology as applied to the interpretation of clinical syndromes as well as with the light cast upon certain physiologic problems by some clinical findings, it has earned a well-deserved reputation as a very valuable handbook for both students and practitioners of medicine.

J. C. CARDWELL

Vital Cardiology.—A New Outlook on the Prevention of Heart Failure. By Bruce Williamson, M.D. Octavo of 344 pages. Baltimore, William Wood & Company, 1934. Cloth, \$5.00.

This book takes as its thesis the view that the essential factors in an efficient action of the heart are rate and force. With this as a background, the various symptoms, pathological changes, and treatment are considered. The book is written from the purely clinical aspect, but the author appears to be well versed in the experimental work relating to the subject. The author expresses the views at which he has arrived as a result of his clinical experiences. Although all of these would not receive universal acceptance most of them are founded on sound reasoning. It is an interesting and well-written volume.

J. HAMILTON CRAWFORD

A Primer for Diabetic Patients.—By Russell M. Wilder, M.D. Fifth Edition. 12 mo. of 172 pages, illustrated. Philadelphia, W. B. Saunders Company, 1934. Cloth, \$1.75.

This primer is intended as a guide for both patient and physician. It has been written in nontechnical language, nevertheless the assistance of a physician will be required for its proper interpretation. No layman with a disease as serious as diabetes should attempt self-treatment. The book is a necessary adjunct to the patient who is working out a life complicated by diabetes under the care of his family physician.

S. GARSON SLO-BODKIN

Handbuch der allgemeinen Hämatologie.—Hrsg. von Dr. Hans Hirschfeld and Dr. Anton Littmair. Band II, Hälfte 2. Octavo of 1627 pages, illustrated. Berlin, Urban & Schwarzenberg, 1934. Paper, Rm. 60.00.

This second half of the second volume of the *Handbook of Hematology* completes what is indeed a monumental contribution to our knowledge of the blood in health and disease. It is a veritable encyclopedia, containing articles on everything of scientific value regarding the hematopoietic system. It is a *sine qua non* to specialists in the morphology and chemistry of the blood, a necessity for hospitals and clinical laboratories. It is a beautiful specimen of the printer's art and the context is written in clear style. The work is too cumbersome for a complete journal review, but numerous articles inspected at random make it clear that it is up to date in all respects.

J. M. VAN COTT

THE PSYCHOGENIC FACTORS IN ASTHMA

C P OBLERNDORF M D

New York City

The respiratory tract is the organ through which we first take in air, which is filled with residual air throughout life and through which we finally expire. It antecedes the alimentary tract in function. From its anatomical position it is closely connected with and embryologically evolved from the gastro-intestinal tract. These two systems are controlled to a very large extent by the autonomic nervous system and are susceptible to the psychic influences of fear, anxiety, and irritation. At times the oral cavity becomes directly a part of the respiratory apparatus. Further, taste and smell have a great psychological influence in affecting both the alimentary and respiratory functions. These senses are so closely allied physiologically and psychologically that occasionally they seem identical.

The factors determining the particular organ affected functionally in cases of psychic conflict have always been a baffling problem, toward the solution of which different types of investigation are being directed. Recently attempts have been made to correlate organ or system function and dysfunction with certain types of disturbance in libidinal development. For instance, Alexander¹ would interpret "the individual's emotional attitude to his environment in terms of the three major tendencies to receive, to retain and to give." He maintains that "the gastric symptoms often express and are conditioned by certain repressed, receptive tendencies—the wish to be taken care of and loved, whereas the intestinal symptoms often are called forth by the positive tendency to give and to be aggressive." He carries the interrelationship of psychic repression and organ dysfunction to its furthest limits in

the theory that peptic ulcer is a lesion found in a specific type of personality.

However, the gastro-intestinal tract is not the only triple function system. The respiratory tract likewise bears a triple duty of intake, retention, and expulsion of a foreign substance. The heart, a purely autonomic organ, also has a similar triple function, although the mind may not regard the blood as foreign. Other organs perform only a double function, intake and expulsion, namely, the nose, the skin, and to a lesser degree the eyes. In contrast with these are the urethra which only expels and the ear which is devoted solely to receiving stimuli. Similarly, the lower alimentary tract is also purely an organ of excretion.

In the psychoanalytic investigation of libido disposition, one finds that a large number of people suffer from the repression of a desire to be loved because attempts to obtain it in early childhood were repelled by parents or their surrogates. Such a narcissistic wound to the ego acts as a potent factor in the structure of many neuroses, even in compulsions and obsessions where conversion symptoms may play a slight rôle. The number of individuals deeply affected by such experience in infancy is so great that it is likely that among persons suffering from gastric ulcer one would find a considerable number of this type of personality. Further, either the respiratory or alimentary systems could equally assume the organic expression of the psychic conflict where the question of intake, retention, or expulsion is concerned. This would be especially likely where the receptive and enusive, passive, and aggressive, feminine and masculine tendencies exist in unstably balanced antagonism.

Based on a case presentation at the Annual Meeting of the Medical Society of the State of New York, Utica, May 15, 1934.

In contrast to such situations of a delicate balance of passive and aggressive tendencies, one would expect in cases of suppressed passivity that a purely receptive organ such as the ear would be psychologically disturbed. That this organ does actually function as a pathway for repressed passive (masochistic) needs may be inferred from the hostile, threatening character of most auditory hallucinations. Even the frequent symptom of ringing or buzzing in the ear may at times be interpreted as a signal of alarm or threat. Expellent organs such as the rectum and urethra would show dysfunction where aggression has been repressed.

The effect of emotional factors on the respiratory apparatus has been described in such conditions as sniffing tics,² the nervous cough, paroxysmal breathing, and asthma. The common cold³ in certain individuals seems to be preceded by (induced by?) mental depression, and pain referred to the accessory sinuses has in recent years become more and more a focusing point for emotional conflict.

In textbook discussions of "asthma," a large number of etiological factors are cited. For instance, Staehelin⁴ mentions inheritance, neuropathic constitution, allergic predisposition, vagotonia and sympathicotonia, arthritic constitution, exudative and eosinophilic liathesis, and exposure to asthmagenic substances, such as horse-hair, hay, and so on, and the connection of asthma with cutaneous disorders; viz., urticaria eczema, and the like. The psychogenic induction of attacks by the smelling of artificial flowers or by the fear of an attack in particular places and climates has frequently been observed. Staehelin records attacks arising after marriage which disappear when the patient is removed from her new home but which recur regularly on returning to the husband's residence.

Psychoanalytic literature contains several cases where detailed studies of unconscious mechanisms have been made and the close resemblance between the symptoms of stuttering and silent sobbing and asthma became apparent. Stegnann⁵ regarded asthma as an anxiety hysteria and Marciniowski also so considered it. Weiss⁶ interpreted the asthmatic attack as a reaction to separation from the mother upon whom the patient was strongly fixated, in a phase of a passive protectivity. He raised the question of the possibility that a sphincteric

anal spasm has been displaced from below upward to the respiratory tract.

When attacks of asthma originally caused by a psychic stimulus have continued over a long period of time they may produce actual organic change in the finer tissue structure of the bronchioles. These in turn predispose to bronchial complications, such as bronchitis, and even susceptibility to a terminal pneumonia.

The case which I shall report was afflicted by an emotional conflict centering about a repressed desire for love from her mother. This conflict seemed to be the strongest influence in the development of a disturbance in breathing which closely simulated asthma. As in most cases of this kind, it is impossible to exclude a constitutional organic weakness as the predisposing factor in the choice of organ affected even though no evidence of early deficiency in the respiratory system exists. However, it will be brought out that an accidental psychic incident may have been the factor fixating the major symptoms in the respiratory rather than in the alimentary tract, although the latter was also affected in its function of elimination.

CASE REPORT

Mrs. Grey, the mother who furnished such an important psychic influence in the life of the patient with asthma (Mrs. White), came under my care first in 1926. Mrs. Grey was at that time aged 56 and had been bedridden for 8 years. During this period she had suffered from "stomach trouble" which had been attributed to gastroptosis in two well-known medical clinics. The fear that she might aggravate the enteroptosis by standing kept her bedridden during all those years even to the extent of using a bed-pan. She had taken all varieties of cathartics and enemas for an obstinate constipation. Her daughter, the future Mrs. White, during all this time acted as a devoted nurse to the invalid mother. The latter was brought to New York on a stretcher from Plainfield, a town of about 10,000 in Ohio. Examination revealed a thoroughly nourished body. Nothing in the medical and neurological examinations or in the history warranted her chronic physical disability.

Investigation disclosed the following family situation. The patient had resided all her life in Plainfield where her father had been one of the prominent citizens.

She married a local man, socially her inferior. Shortly after the marriage she realized that she could never expect any success from her husband and took command of the family situation. The precarious financial condition of the family became chronic when about 8 years after their marriage Mr. Grey suffered from an illness for 3 years. Still Mrs. Grey exerted every effort for 20 years to retain a social position with her girlhood friends who had married more fortunately.

At the end of this period an event occurred which effectually shattered any hopes which she had retained for the rehabilitation of the family's social status. Her elder unmarried daughter, Mary, aged 20, became pregnant but the condition was not diagnosed until 5 months had passed. The predicament was solved by a forced marriage but the birth of a full-term child 4 months later furnished the town scandal and a crushing humiliation for Mrs. Grey. For 3 years she attempted bravely, even defiantly, to associate with intimate friends as though nothing had happened but the gastric distress in 1918 forced her to bed.

On suspecting this obviously probable causation, the author directed his efforts toward convincing the patient that such a flight into illness was unnecessary—that she could walk without great danger to herself—that her friends would respect her more well than sick, and so on. A few therapeutic conversations, supplemented by the tactful assistance of a nurse conversant with the situation, resulted in a dramatic recovery. She arose from bed, walked to the office and a month later the author saw her at her daughter's home merely to pronounce her cured.

Developments of the Asthmatic Illness.

Although from time to time the author had reminisced of the brilliant result, he heard nothing further of the patient until January, 1933, when her son-in-law, Mr. White, called to consult in regard to his wife's asthma. He reported that Mrs. Grey had been well for seven years, but from the observation of his mother-in-law's previous illness he had come to the conclusion that the asthma of Mrs. White might be a neurosis.

The history of the onset of his wife's illness was the following. Mr. White had returned from a business trip in October, 1930, with a "cold" which his doctor diagnosed as hayfever. Shortly thereafter—

about January, 1931—Mrs. White, aged 30, developed shortness of breath and a cough which a physician said was allied to asthma. She was under care of physicians continuously from January until April, 1931, when she had her first real asthmatic attack which confined her to bed for 5 weeks. She showed positive skin reactions to corn, cabbage, chicken, to dog's hair, and cat's fur. She had carefully avoided indulgence in or contact with these substances for two years with no relief of her symptoms. In April, 1931, her father, Mr. Grey, lost his position and Mr. White reluctantly assented to Mr. and Mrs. Grey's coming East to live with them. They took up their residence in the White household in July, 1931.

Although Mrs. White was up and about during the summer of 1931 she took from one to three hypodermics of adrenalin daily. In August, 1932, another attack occurred so severe that she could not cross the room because of shortness of breath. Mrs. Grey, still well and active, reversed her former rôle of patient and began to nurse the daughter day and night. Another violent attack in September, 1932, occurred while the patient was in the mountains where she had been sent for her asthma. During the early autumn of 1932 the patient was somewhat better but in October she became increasingly irritable and nervous and took to her bed until December. At that time she practically had attacks continuously, so severe that she was unable to leave her bed and was taking huge amounts of medication of a sedative nature and adrenalin hypodermically. She would inhale chloroform to induce unconsciousness and on several occasions had burned her face severely.

When the patient came under the author's charge in January, 1933, she weighed about 80 pounds, had been receiving intravenous injections of glucose, and seemed moribund. She assumed a very unusual position in bed. She sat with her legs folded underneath her perineum. One of the nurses observed that her heel was pressed very tightly against the vagina. She was bent over so that her head touched the bed. The rhythmic spasmodic contraction of the muscles of her neck bore no relation at all to her breathing. The latter was normal in frequency. However, expiration was accompanied by a wheezing sound. Her condition was so alarming that an internist was called in consultation so

that it might be determined if the withdrawal of drugs would be fatal. After considerable deliberation it was decided that the attempt should be made. The substitution of sterile hypodermics for adrenalin and inert preparations for the hypnotics and sedatives soon demonstrated that these potent drugs exerted little or no influence on the course of the illness, and so were gradually abandoned.

The progress toward recovery was extremely slow but it was demonstrated to both the patient and her husband that the attacks were entirely dependent upon reaction to psychic difficulties and that a hitherto unrecognized neurosis of her husband played a great rôle in the production of the wife's condition. The husband, although over-solicitous concerning his wife's health, showed no signs of affection for her, spoke to her only in short sentences and was exceedingly eager to be away from her presence. The wife soon began to openly complain of her husband's sexual indifference. He, too, entered treatment.

Early Family Background. Mrs. White, the daughter of Mrs. Grey, was the youngest of 3 children. It was the elder sister, Mary, who became illegitimately pregnant when the patient was about 12 years old. A brother, 4 years older than the patient, died at the age of 22 years. Mr. Grey, the father, was an extremely religious man, a lay preacher, lacking in energy and drive, and dominated by his wife. Mrs. Grey, the mother, proud of her distinguished local ancestry, had striven ever since her disappointing marriage to maintain her hereditary position.

As a child Mrs. White had been subject to tantrums and violent outbursts of temper. Her mother had raised the children with the greatest regard for the conventions. The patient from early childhood was discontented with herself because of her mother's high standards but made every effort to become popular. She was so self-conscious that she could never give a party in her own home and was intensely sensitive to any criticism. The patient relates that she had been so obsessed by false ideas of conduct that when at the age of 12 she visited a friend in another city, she did not use the toilet for defecation over a period of 8 days because she feared that the odor might be detected. She frequently would not urinate for a day.

She shared the extreme humiliation of her mother when her sister, Mary, became pregnant. External changes in her character now began to show themselves which seemed in contrast to her modesty and repression. From that time onward apparently she not only assumed the mother's rôle of upholding the honor of the family but also the rôle of father because of the latter's ineptitude. Even before she became the father of the family she was boyish in many of her interests and mannerisms and carried a boy's nickname up to the time she came for treatment.

When her mother took to bed in 1918 the patient assumed the entire care of the mother, including the function of bed-pan carrier. The patient consciously realized that the rôle of martyr was not without its advantages, for much as she disliked attending her mother, she received praise for it and often used it as an excuse to avoid more disagreeable duties and social obligations.

Mr. White was the brother of one of Miss Grey's girlhood friends. He also came from an extremely formal family where the mother played an important rôle. His father, a Methodist minister, was a man of some force. The White family, too, was proud of its social position although not quite to the same degree as the Greys. Mr. White had an intense family loyalty, so much so that while at college and for 10 years following he never missed returning home to his mother for summer vacations. He was extremely devoted to his work, political economy, at which he gradually achieved success. Up to the time he had married at 35 he had never had relations but was still indulging in masturbation. His social contacts with women had been few and superficial.

Our asthmatic patient had seen very little of Mr. White who was about 10 years her senior because he did not reside in the same town. It was a case of love at first sight but the question of marriage remained for some time in doubt because the patient felt it her duty not to forsake her bed-ridden mother. Finally, the wedding ceremony took place at the mother's bedside in 1925.

Mr. White's work made it necessary for him to establish his home in Albany at the time of marriage. His sexual contacts with his wife were infrequent and unsatisfactory because of his prematurity. From the very

beginning of their residence his wife insisted on returning to Ohio every two months to see her mother. Her intense concern and anxiety finally led to the trip of the bedridden mother to the East for consultation in 1926. After the mother's recovery she came to visit her daughter frequently. The author is now inclined to attribute Mrs. Grey's remarkable recovery not primarily to his explanations and reassurance. An unconscious reaction motivated by the gain which would accrue to the mother through visiting her daughter dispelled the previous secondary gain through illness. Because of Mr. White's disapprobation it had become increasingly difficult for the daughter to return so often to her mother, but the restoration of her mother's health made it possible for her to accept the burden of travel.

The married life of the young Whites on the surface appeared placid and happy. However, no real mingling of interests occurred between the reserved Mr. White and his energetic, ambitious wife who continued intent upon the preservation of the traditions of the Grey family. About 3 years after marriage a child was born who died almost immediately. Shortly thereafter Mrs. White became pregnant a second time and gave birth to a boy. She claims that during her pregnancy she was proud of her condition. After the child was born she became extremely oversolicitous of him.

At the time she came for treatment she had developed a strong hatred of the boy, then aged 3, whom she would punish by spanking and over correct continually. Mr. Grey became impoverished so that the support of Mrs. White's parents devolved upon her husband. When they came to live with the young couple, the husband became more reserved, less communicative to his wife, and retired more and more within himself. On the other hand, Mr. White's parents, especially the mother, became more and more critical in their letters of the Greys and young Mrs. White. The mere mention of her mother-in-law would cause an intense outburst of suppressed rage in Mrs. White. Yet, she feared to attack her mother-in-law because of her husband's attachment to his mother.

ANALYTIC INTERPRETATIONS

In the course of the analysis it became apparent that the patient's exaggerated

anxiety for her mother represented an overcompensation for intense hostility based upon the patient's resentment to her own sex. Although the daughter made much of her desire to care for the mother, she hated the irksome tasks, especially the emptying of bed-pans, for the eight years that her mother was ill. The illegitimate pregnancy of her sister may be regarded as the external circumstance which precipitated the neurosis of both the mother and daughter. While consciously condemning the erring sister, Mrs. White secretly envied her because she saw in her sister's condition a fulfillment of heterosexuality which she believed she could not attain. As a protection against the possibility of following in her sister's footsteps, she began more and more to identify herself with the male. When the family financial situation became stringent, the patient replaced the father.

The patient suffered from inner tension from the age of 5 or 6. She would not remain at a stranger's house over night because of her worry over defecation, nor could she evacuate if there were people nearby in her own home. On the other hand, she had no feeling of disgust if people defecated before her. Her bowels had not moved without cathartics for over 16 years. The analysis disclosed that the patient held the infantile theory of birth per rectum which equates the constipation with denial of child birth. The constipation may, however, also be interpreted as signifying an overcompensation for a desire to vent her resentment on the world at large.

When the patient came for treatment it was noticed that the nipples of her small breasts were usually in a state of erection and well developed. The patient subsequently stated that she had always been extremely ashamed of her breasts as indicative of her sex and had bound them tight to prevent their growth. She wore a menstrual pad, bound tightly, day and night when not menstruating.

As evidence of similar suppression it must be mentioned that the patient almost never cried because she considered it a feminine trait. When her brother died her lids became pimply and red which the family doctor attributed to the fact that she suppressed weeping.

The choice of mate in marriage was unconsciously determined on both sides by the mutual recognition of complementary

qualities in each party. The wife began to assume the masculine rôle in the couple's infrequent relations. She also found it possible to avoid too long association with her husband by frequent trips to the mother—all of which suited the husband.

The birth of the child after four years of married life tended to bring about the first definite rift. From the analytic interpretation, the child, in addition to removing her from her husband, represented definite evidence of her femininity and a sin like her sister's. Prior to the birth Mr. White had been engaged in a field of economics which did not interest him. He had been dissatisfied with both his work and remuneration and had turned to his wife for commiseration. Just before the child was born he received a position entirely to his liking which absorbed all his interest. This permitted him to revert to a life which was almost asexual but which because of the increased opportunity for sublimation he found acceptable. A change in her husband at this time made the acceptance of motherhood more difficult for the patient.

It will be remembered that the husband suffered first from some type of nasal affliction, diagnosed hayfever, and shortly thereafter the patient began her attacks. This accidental circumstance furnished a determinant for the form of the patient's illness. The identification with masculinity caused her to unconsciously adopt the husband's symptoms which were nasal (nose equates penis).²

It is also possible to point to an accidental psychic factor in early childhood as a determinant of the later consequence—asthma. When the Greys were compelled to vacate the ancestral home, it was bought by an old gentleman with asthma. The patient, then about six, was mystified and fascinated by the old gentleman's dramatic attacks. It was, to her, an aristocratic disease belonging to the rich man who succeeded her unsuccessful father. In other words, a disease characteristic of men and found in the wealthy—fashionable in much the same sense as appendicitis thirty years ago or sinusitis today. It is conceivable that this early impression reactivated by her husband's hayfever accounts for the choice of respiratory expression of her conflict between aggression and passivity.

In her personal relationship to Mr. White there existed good reason for resentment to him. Soon after marriage

she began to harbor antagonism because of his over-attachment to his mother and his failure in marital obligations. It was fed by her own unconscious homosexuality. At the same time the sense of guilt for the unconscious antagonism to her mother kept alive an overwhelming overcompensatory compulsive desire to defend and serve her. The painful dilemma in which the patient found herself now becomes apparent. The mere mention of the White family makes her "wish to explode." A counter impulse checks this tendency and causes her to hold her tongue and her breath. The compromise attempt results in the wheezing symptom called asthma. The patient remarked that when the attacks ceased the sensation of inner tension increased and the muscles in the back of the neck became more taut.

Let us recall that while at home the patient was the head of the house and proud of it. Here the unconscious masculinity had free play. The old home represented domination in her masculine rôle; the home with her husband implied the assumption of femininity. The attack then becomes a struggle between two forces which may be designated by the terms aggression and submission, expulsion and reception, sadism and masochism. The patient's unconscious gain through illness is revenge against both her mother and husband at the cost of almost inconceivable self-punishment.

Course of the Illness. Obviously, one could not expect any permanent results in the symptomatic cure of Mrs. White's illness without a change in her husband. His analysis indicated that he suffered from that form of psychic impotence dependent upon unconscious identification with the mother. The depth and the intensity of the attachment to his mother and its influence upon his sexual life had never been conscious to Mr. White. He had believed that the interest was all on his mother's side, and while it was true that the mother entertained jealousy toward young Mrs. White, it was equally true that her interest in him was superficial.

The most difficult actual task concerned the separation of the patient from her mother who had been living at the patient's home for two years. The thought of separation or the discussion with the husband of financial arrangements for the Greys would throw her into violent breathing attacks. Finally, it was agreed after four

months of treatment that Mrs. Grey leave her daughter. By this time both Mrs. White and her husband had gained sufficient insight into the psychogenic nature of their trouble to co-operate with each other and with the physician.

One of the most critical phases concerned the withdrawal of the hypodermics. The patient had regarded them as her talisman and the information that sterile water had been substituted for adrenalin alarmed her, as the deprivation of a guiding hand might terrify a child crossing the street. Gradually, the intervals between attacks became longer and the couple were able to go on an automobile trip in August, 1933. However, the attachment to the mother was not broken and again before Christmas the patient fell into tremendous conflict between the desire to stay with her husband and to return to Plainfield. The conflict soon found expression in respiratory symptoms which now for the first time resulted in a true bronchopneumonia.

After January 1, 1934, the author's contact with the case became intermittent. When she recovered from the bronchopneumonia the asthma was replaced by periods of mental unrest closely resembling manic excitement which lasted about a month. She talked a great deal, particularly concerning her wish for her mother to return and the shortcomings of her husband.

Certain practical considerations interfered with the treatment. The patient resided at some distance from New York so that the cost and difficulty of transportation in addition to the cost of treatment began to weigh heavily upon her. It reinforced the general worry about the financial obligations to her parents in which the marriage had involved her husband. The husband, under the necessity of earning a livelihood, was compelled to be away from home much of the time and could come only irregularly for his own treatment. The patient felt that he was neglecting his responsibility in the situation and that the author indulged him in this direction.

When doubt assailed her in connection with her divided allegiance, the increased breathing returned. It became acute in May, 1934. She reverted to rash injections of adrenalin and strong sedatives. During this time her only attendant at home was a well-meaning but ill-advised Irish maid who gave medication freely. Her family physician called from time to

time and saw her shortly before her death in June. The death which occurred suddenly was ascribed by her physician to "choking following the aspiration of mucus."

COMMENT

The sequence of change in libidinal expression in this case was the following: identification with the mother, denial of love by the mother which induced antagonism, subsequent identification with the father with repressed overcompensated hostility to the mother, a strong unconscious aggressive urge opposing an equally strong conscious passivity. The outstanding feature is the inability to yield completely to the desire to be loved by the husband and a suppression of the impulse to love (hate) her mother.

Although fatal termination occurred in June, 1934, it must be recalled that the death of Mrs. White through exhaustion seemed imminent in January, 1933, when the psychological approach was adopted. In spite of the fatal outcome this much was demonstrated during the year and a half which preceded her death: (1) That psychological stimuli set the attacks in motion; (2) that the so-called specific allergic determinants had nothing to do with the attacks. She ate chicken freely, likewise corn and cabbage in season. The presence of cats and dogs in her own home did not induce attacks, notwithstanding her positive reaction to the fur of both these animals; (3) that the asthmatic attacks were substituted by emotional outbursts quite like manic attacks.

Through the psychological approach a new basis for the understanding of the illness of both husband and wife was introduced. From the theoretical aspect a solution of the psychological factors could have occurred had not practical difficulties interfered. Mr. White's relative impotence was only partially cured but even with a small amount of treatment his confidence in himself increased and also his business capacity in many directions.

In conclusion one may say that psychoanalytically the asthmatic attack represented the cry of the infant for the return of the mother only in a most superficial interpretation. At a deeper level of mentation it is a manifestation of a conflict concerning emission and reception, domination and submission, unconscious masculinity and conscious femininity. In its immediate

form the conflict was one of conscious submissiveness to the mother and unconscious desire to dominate her; conscious reverence for the husband with an unconscious desire likewise to dominate him.

KEEP AN EYE ON ALBANY

The State Legislature has convened for what may be a momentous session. For one thing, the friends of health insurance are almost sure to introduce a bill to make it law in this state. And, adds the *New York Medical Week*, this is not the only threat confronting the profession. If it were not for Governor Lehman's courageous veto, the osteopaths would have succeeded last year in putting a law upon the statute books empowering them to employ drugs and perform surgery. They are not going to let this year go by without making another attempt. The antivivisectionists will seek to cripple scientific investigation by barring dogs from research laboratories. Physiotherapy technicians, chiropractors, cosmetologists, and who knows what others, will try to destroy the force of the

Medical Practice Act. They will bear watching.

Equalled only by health insurance in its importance to physicians, the Workmen's Compensation Act will undoubtedly come up before this Legislature for revision. The profession is vitally interested in enactment of the reforms advocated by the Governor's Medical Advisory Committee and in blocking any attempts, by the State Fund or any other group, to set up a monopoly in the treatment of this class of patients.

Medicine must be prepared to act, and to act promptly, to defend its rights. Collective action by professional organizations will not suffice unless physicians in the capacity of individual citizens bring the pressure of their opinion and that of their lay friends to bear upon the legislators at Albany.

ON GETTING STARTED

To gain the recognition of a community and to win its confidence as a practitioner of medicine and surgery is a task not easy, nor quickly accomplished. The mere making of a living and the amassment of money is the least of its features. Money can be made by any mountebank; such is the ignorance and credulity of men in general that anyone with assurance, who is willing to reiterate with sufficient positiveness and repetition even the most groundless and absurd claims, can obtain for a time the credence of a multitude, will draw after him a following and may coin his pretences and their credulity into riches. The methods of the market place, the strife of the exchange, the standards of commerce and trade, the advertising columns of the public press, the practices of the political platform, the enlistment under the banner of a special creed for which claims of peculiar efficacy are made, are however, all so inconsistent with the essential nature of medicine as a science, and with the peculiar personal intimacy of the duties and the sacredness of the relations of the physician in the practice of his art that they have always and everywhere been regarded a repugnant to the true spirit of the medical profession and have been repudiated by high-minded physicians.

Invariably just so far as they are resorted to by individuals who are striving to gain the confidence of a community as practitioners of the

healing art, do such individuals lose the special regard due them as physicians, while at the same time they diminish the respect with which that calling as a class has always been regarded. To bring help to a suffering fellowman, to devote one's life to the attainment of the highest possible skill and excellence in such a calling, such a thing truly is worthy of the highest praise and sure to command the admiration of men as long as men must suffer and die! Every true physician is therefore a priest serving at the altars of Humanity.

There is, however, to the physician's life another and more practical side that cannot be ignored. A high ideal of the character of one's profession does not of itself bring bread and butter to the struggling devotee. To provide for one's family, and to forestall the needs of the days of lessened ability and acceptability that come with advanced years, is a duty equally sacred with the special claims of his calling. In all countries and ages it has been ordained that a priest should live of the altar. There is nothing inconsistent therefore in the expectation of the physician that there should come to him freely from the recipients of his skill and attention, a return measured only by the importance of the service which has been rendered and by the ability to give of the person served.—(L. S. PILCHER, in *A Surgical Pilgrim's Progress*, 1894.)

THE NON-DRAINAGE TREATMENT OF PERITONITIS

G W COTTIS M D I A C S and H W INGHAM M D

Journal of the American Medical Association

ABSTRACT

The purpose of this paper is to call attention to well established facts concerning peritonitis and to urge a wider application of physiologic principles in the treatment of this disease.

We are prone to forget that before the present era of abdominal surgery many patients recovered from peritonitis without operation. Perforated ulcers of the stomach and duodenum were closed by adhesions, appendiceal abscesses ruptured into the cecum, pelvic peritonitis became localized and the pus was absorbed or rendered sterile, all by action of normal peritoneal defenses. The important point is that recovery depended on a quarantine of the infecting lesion. If adhesions failed to stop the stream of infectious material, the patient died. It was only when continuous reinfection was halted that recovery ensued.

The advent of modern surgery brought a great reduction in the mortality of all types of peritonitis. Removal of the source of infection was always accompanied by drainage and often by quarantine packs. The only exception was in tuberculous peritonitis in which the invariably fatal result of drainage soon led to its discontinuance. It was discovered that in this disease the mere opening of the abdomen, with evacuation of the ascitic fluid and closure without drainage resulted in a high percentage of cures. There seemed to be no rational explanation and surgeons accepted it as a fact *sui generis*, unique and with no bearing on other forms of peritonitis.

Few if any attempts were made to apply the same treatment to ordinary pyogenic peritonitis until about the third year of the World War. At that time, British Army surgeons made their epochal discovery that multiple perforating wounds of the intestines were almost always fatal when treated by drainage either with or without suture of the perforations, but that careful suture of the perforations, flushing of the peritoneal cavity, and closure without drainage reduced the mortality to between 50 and 60 per cent.

About thirty years ago Ochsner had a prophetic glimpse of the truth when he

advocated his starvation treatment of appendicitis with delayed operation. He realized that the peritoneum could be trusted to take care of widespread infection and to wall off an abscess in the region of the perforated appendix. It seems strange now that nobody took the next logical step by using the same treatment *after* instead of before the removal of the source of infection. Today we know that the same peritoneal resistance which in the Ochsner treatment overcomes a spreading peritonitis is hampered rather than aided by drainage tubes.

Why is drainage so generally attempted? Medical historians will some day point to the era of promiscuous drainage, now happily ending, as an example of surgical meretriciousness. Its futility in diffuse peritonitis has been repeatedly proven both clinically and experimentally. To justify this statement we would call attention to some of the recorded data.

In 1905, Yates¹ demonstrated the inefficiency of cigarette drains in the peritoneal cavity. The drains were always promptly walled off.

In 1917 the startling reduction in mortality which followed discontinuance of drainage by surgeons of the Royal Army Medical Corps has already been mentioned.

In 1919, Hertzler² using methylene blue in an albumen solution found that drainage ceased in less than eight hours. He cites the similar results obtained by Petroff and others, all showing that drains were completely isolated from the general peritoneal cavity in from six to forty eight hours.

In 1924, Sir Henry Gray³ published a discussion of the whole problem of drainage. His paper is a most logical summary of conclusions drawn from a vast experience in both civil and military surgery. He is emphatically opposed to drainage in peritonitis except in (1) cases of persistent oozing of blood from the surface of an abscess cavity and a condition of the patient necessitating rapid operation, and (2) a shaggy irregular lining covering the surface of the abscess. He stresses the importance of removing the source of in-

fection, and says, "Intra-abdominal drains do not drain the abdominal cavity except the small part which they themselves are irritating. The rest of the cavity is quickly shut off by the formation of adhesions."

In 1932 Shipley and Bailey⁴ reported having four patients who after operation for appendiceal peritonitis developed mechanical obstruction due to angulation of an intestinal loop in the drainage tract. Two of them died. In all four cases they found that "the remainder of the peritoneum was free of adhesions or any evidence of peritonitis." Following this experience they operated without drainage on forty-eight patients with early peritonitis either local, spreading or diffuse with no deaths and no serious complications.

Marchini⁵ reported a series of 443 cases of peritonitis of which 301 were localized and 142 were diffuse. Of the total number 285 were drained, with 40 deaths, a mortality of 14 per cent. The remaining 158 were not drained and 9 died, a mortality of less than 6 per cent.

Mensing⁶ states:

Drainage of the peritoneal cavity in cases of generalized peritonitis is generally ineffective and is usually harmful. . . . The futility of drainage in general peritonitis is readily seen when it is recalled that the peritoneal cavity cannot be drained in the ordinary case of general peritonitis and that contamination of the blood stream by bacteria and their toxins had occurred long before drainage was instituted.

These clinical reports accord perfectly with the results of animal experimentation. Dixon and Rixford⁷ have shown that normal peritoneal fluid contains about 2,300 white cells per cu.m.m. Inflammation increases the number, first of neutrophiles and later of histiocytes, which are still more powerfully phagocytic. In forty-eight hours after the injection of mixed streptococcus and colon bacillus vaccine the white count averaged 44,300. In one patient, the peritoneal cell count rose from 3,370 to 163,000, forty-eight hours after vaccination.

In 1931 Buchbinder, Droegmueller, and Heilman⁸ in a series of experiments demonstrated the importance of removing a septic focus and of closing without drains. To provide a septic focus they opened a loop of bowel and made an end to end anastomosis of the segments above and below the section. Of 31 animals so treated, 90 per cent died of peritonitis. They then

repeated the experiment on 33 animals, but at the end of 24 hours removed the source of infection by excising the open loop of bowel and closing the abdominal incision. Of these animals, 14 recovered.

In a third series of 20 animals the same two operations were performed except that two drainage tubes were inserted, one in the upper abdomen and one to the pelvis. All of these animals died, two during operation, the others after an average period of four days.

Many other competent surgeons have reported improved results after they have abandoned drainage. We have been able to find no report of higher mortality following omission of drains. In January, 1929, we rather tentatively began to eliminate drainage in operations for peritonitis. At first we closed the peritoneum in cases of gangrenous appendicitis without gross perforation but with turbid peritoneal fluid. It was at once apparent that with these patients our results were better than when we had drained. However, in some cases where we closed the skin completely or around a subcutaneous drain, infection of the fatty or aponeurotic tissues appeared in from 3 to 5 days. Permeability of the gangrenous wall of the appendix permitted infection of these relatively non-resistant tissues. Then we closed the muscles loosely and packed the entire outer wound with B. I. P. gauze. When this gauze was removed in three or four days we almost always found a clean granulating wound which could be safely closed with interrupted silk or silkworm gut sutures.

The next step was the closure of the peritoneum in cases of perforation with free purulent fluid and no adhesions. In spite of our conviction that this was a logical procedure we were amazed to find that the temperature dropped to normal in from 24 to 72 hours, and that the postoperative courses did not differ from that of simple acute appendicitis.

We have analyzed our last 250 cases of acute appendicitis with special attention to the mortality in relation to the state of the disease and to the causes of death.

Cases of uncomplicated acute appendicitis constitute the first class. There was gross evidence of inflammation including one or more of the following: Redness, swelling, pus in lumen, ulceration or diffuse necrosis of mucosa, fresh omental adhesions, free peritoneal fluid. Except in a

few of the earlier cases, all of these were closed without drainage

There were 155 of these cases with no deaths

In the second class were 41 cases of gangrenous appendicitis with involvement

of the peritoneal coat but with no gross perforation. Of these 5 were drained because the appendix was retrocecal or retroperitoneal; 8 had localized suppurative peritonitis. All of these were drained for a few days. Three had diffuse spreading

TABLE I DEATHS FOLLOWING DRAINAGE

Age Case No	History	Findings	Operation	Date of operation	Date of death	Comment
I Age 50	Onset 4 days before operation Diagnosis Pelvic peritonitis probably from diverticulitis of sigmoid	Lower half of abdomen full of thin purulent fluid. No adhesions. Gangrenous and perforated appendix hanging over promontory. Intestines red and distended.	Midline incision. Appendix removed. Large cigarette drain to pelvis. Enterostomy.	May 8 1927	May 26	See comment below
II Age 49	Pain tenderness in gallbladder region 4 days before admission. Vomiting, fever, and tenderness over appendix 3 days later.	Abdomen full of thin turbid fluid. No adhesions. Perforated appendix at outer side of cecum. Gallbladder acutely inflamed and covered with fibrin.	Right rectus incision. Appendix and gallbladder removed. Large cigarette drain to appendix stump. Spreading gangrene of abdominal wall. Disruption of wound on 9th day with escape of bowel. Stinking necrotic fascia removed. Bowel replaced with silk worm gut. Closure with spreading necrosis until death two weeks later.	April 10 1929	May 5	Spreading gangrene of abdominal wall
III Age 35	Physician's wife. Severe type of diabetes. Recurrent appendicitis for 2 years. Sensitive mass with pain and fever for 2 weeks before operation.	Large bulging abscess below right costal border, well walled off.	Procaine anesthesia. Vertical incision. Peritoneum nicked with knife. Gush of stinking pus under pressure. Cavity explored with finger. Appendix not found. Large rubber tube drain.	Sept 14 1929	Sept 29	Coma
IV Age 3	Onset 4 days before admission. Catharsis and enemas. Ileus, vomiting, and cyanosis on admission. Abdomen distended.	Abdomen full of thin yellow fluid. Intestines red and distended. Perforated appendix lying outside of cecum. Surrounded by large abscess full of thick stinking pus. Patient in extremis.	McBurney incision. Appendix removed. Wound left wide open. Abscess cavity packed with gauze.	Feb 2 1932	Feb 4	No improvement. Death from toxemia.
V Age 63	History of gallstone colic. Pain and nausea for 48 hours before admission. No signs of peritonitis.	Gallbladder full of stones. Large retrocecal abscess around gangrenous appendix. No peritonitis.	Right rectus incision. Abscess cavity opened by incising parietal peritoneum just below cecum. Ureter and iliac vessels exposed. Appendix inaccessible, not removed. Large rubber drain through stab wound.	Aug 11 1932	Aug 15	Progressive toxemia.
VI Age 44	Acute onset 10 days before admission. Remission after 3 days. Return of pain, vomiting and fever after catharsis.	Stinking thin pus filling abdominal cavity. No adhesions. Several fecaliths free in abdomen. Appendix necrotic and separated from cecum with large opening in cecum discharging feces.	Midline incision. Cecum closed with purse string suture. Pelvis flushed with saline. Large cigarette drain to cul de sac.	Oct 1 1932	Oct 2	General peritonitis. Moribund on admission.
VII Age 47	Acute abdominal pain and nausea for three days before admission. Cathartics and enemas.	Appendix completely gangrenous. Large perforation. No adhesions. Abdomen full of thin stinking pus and feces. Adjacent peritoneum grey and necrotic.	McBurney incision. Appendix removed. Wound left wide open and packed with gauze.	Nov 11 1933	Nov 14	Progressive toxemia.
VIII Age 39	Pain in right lumbar region for 7 days. Patient walked in. Palpable tender mass in right loin. Temp 99.	Large abscess cavity behind cecum, containing gangrenous and perforated appendix. No peritonitis. 4 days later diarrhea with foul black liquid stools. Vomiting relieved by nasal suction. Sphagea. No fever. Death from exhaustion. Autopsy showed multiple thrombi of mesentery with necrosis of mucosa. Small bowel filled with black liquid blood.	McBurney incision. Outer leaf of mesocolon divided. Appendix removed. Abscess cavity sponged and packed with gauze. Wound left wide open. Black stinking fluid after removal of pack on 3rd day. Blood transfusion intravenous glucose repeatedly. Cecostomy on 9th day. Mucosa dark purple color.	Jan 11 1934	Jan 26	Multiple mesenteric thrombi with venous bleeding from bowel. Death from hemorrhage and starvation.
IX Age 58	Sudden epigastric pain 30 hours before admission. Question of perforated ulcer or appendicitis.	Thin purulent fluid filling abdomen. No adhesions. Appendix retrocecal. Gangrenous and perforated.	" "	April 4 1934	April 6	Toxemia.

peritonitis. Two of these were among our earlier cases and were drained; one was not. Combining the figures for this group, 15 were drained and 26 were not. There were no deaths in this series.

The third series is constituted of 54 cases of perforative appendicitis with gross leakage of appendiceal contents. In 27, or one-half of these patients, the peritonitis was limited by adhesions although in some of them the pus filled the pelvis or a large part of the right half of the abdomen. Of these 17 were drained with 4 deaths, a mortality of 23.5 per cent. Ten were not drained and one died. Mortality, 10 per cent.

The other 27 patients all had diffuse spreading peritonitis with no discoverable walling off; 11 were drained with 5 deaths (mortality 45.5 per cent); 16 were not drained and 2 died (mortality 12.5 per cent). It is significant that of the three undrained fatal cases, none died of peritonitis, although one death may justly be charged to our failure to realize that drainage was indicated. (See Table II, Case XI.)

Combining the figures for localized and diffuse peritonitis, we find that 28 were drained, with 9 deaths (mortality 32.15 per cent); 26 were not drained, with 3 deaths (mortality 11.11 per cent).

Since 3 of the drained cases were prac-

tically moribund and because some of the deaths were apparently inevitable with or without drainage, a more accurate evaluation of drainage may be obtained by eliminating these cases from our compilation. Admitting the debatability of our selection, we feel that it is proper to omit Cases II, III, IV, V, VI, VIII, X, XII. The revised figures would then be: 22 cases drained, with 3 deaths (mortality 13.6 per cent); 24 cases not drained, with 1 death (mortality 4.17 per cent). It is interesting to note that the one death in the undrained series resulted from an entirely extraperitoneal infection after all of the peritonitis had disappeared. (See Table II, Case XI.)

The tables show the salient features of each of the fatal cases. In the light of our more recent experience there are some points in regard to the cases worthy of comment.

CASE I.—Here the error in diagnosis resulted in a midline incision. Enterostomy is still advocated by some surgeons as a routine in similar cases. With a McBurney incision, no enterostomy and closure of the peritoneum this patient would have had a better chance to survive.

CASE II.—This was a typical case of spreading gangrene of the abdominal wall occurring before cautery excision was known to us. With present-day treatment this patient probably would have been saved. Peritoneal drainage was not a factor.

CASE III.—Diabetic death after patient returned to her home. No question about drainage.

TABLE II. DEATHS FOLLOWING NON-DRAINAGE

Age Case No.	History	Findings	Operation	Date of operation	Date of death. Comment
X Age 27.	7½ months pregnant. Upper abdominal pain for 3 days before admission. Gallstones suspected.	Perforated appendix lying at outer side of colon. Tip pointing upward. Stinking thin pus filling right side of abdomen.	Transverse incision. Pus removed with moist gauze sponges. Peritoneum and muscles closed. Wound packed with Bipp gauze.	July 11 1932	July 18. Apparently convalescent when miscarriage occurred on 7th day followed by collapse and death.
XI Age 35.	Left abdominal pain for 3 days.	Appendix gangrenous and perforated. Entirely retroperitoneal under root of mesentery. Tip lying anterior to dorsal vertebrae. Entire abdomen full of thin pus. No adhesions.	McBurney incision. Appendix removed, exposing retroperitoneal tissues. Fluid aspirated. Incision closed. Ileus with persistent vomiting on 3rd day. Relieved by nasal suction siphon. Temperature rising. Exploratory operation on 6th day. Peritoneal cavity normal. No fluid. No adhesions. Peritoneum normal. Large retroperitoneal abscess opened and drained.	Aug. 10 Aug. 16 1933	Aug. 18. Ileus and toxemia.
XII Age 60.	Acute abdominal pain with distension and obstipation 48 hours before admission. Suggestive of obstruction. No fever.	Appendix low in pelvis, gangrenous and perforated. Lower half of abdomen full of thin purulent fluid.	Midline incision. Appendix removed. Pus aspirated. Peritoneum closed. Complete suppression of urine from time of operation. Severe vomiting with disruption of wound on 4th day. Peritoneum found normal. No pus present.	Sept. 17 1932	Sept. 24. Uremia.

CASE IV—Hopelessly toxic Death probably inevitable with or without operation and with or without drainage

CASE V—This case illustrates an important point With wide exposure of retroperitoneal tissues to infection, free drainage is imperative A correct diagnosis with McBurney incision left wide open would give much better prognosis Strikingly wound drainage is rarely effective where real drainage is required Also with McBurney incision appendix could be removed

CASES VI AND VII—Same as Case IV

CASE VIII—Autopsy proved absence of peritonitis Mesenteric thrombi, involving large areas of bowel from cecum to jejunum, constituted a complication unavoidable and incurable

CASE IX—Same comment as on Case V

CASE X—Peritonitis apparently subsided without drainage Sudden emptying of uterus, always serious, was fatal in this case

CASE XI—This patient should have been drained While the peritonitis was completely cured by removal of the appendix and closure without drainage the retroperitoneal abscess, discovered with difficulty even at second operation resulted in ileus, to which treatment was directed Location under root of mesentery perhaps a factor in neurogenic paralysis? This is the only case in which we have regretted the omission of a drain

CASE XII—Despite widespread peritonitis, secondary operation for disruption of wound revealed a normal peritoneum four days after removal of appendix and closure without drainage Urinary suppression commencing at time of operation could not be related to question of drainage

Since appendicitis is the greatest single cause of peritonitis a description of our technic in appendicectomy may be justified as illustrating the principles of treatment in all types of peritonitis

INCISION

The importance of this step is often underestimated The right rectus incision may be necessary for examination of the gallbladder, stomach, and pelvic organs, but acute appendicitis does not justify a roving commission Furthermore a positive diagnosis of acute appendicitis should be possible in most cases, and the first consideration should be direct approach rather than exploration The McBurney incision gives the most direct access to the appendix with minimum exposure of the peritoneum In seven of our twelve fatal cases the appendix was found at the outer side of the cecum or entirely in the retrocecal space These appendices cannot be reached through a rectus incision except at the cost of forcible retraction and harmful packing of the intestines

On the contrary with a McBurney in-

cision a walled off abscess in this location can often be opened, the appendix removed and the wound closed without invading the general peritoneal cavity at all If the abscess is retrocecal or if profuse oozing of blood precludes closure, the best possible drainage is permitted by leaving the wound wide open By a McBurney incision we do not mean the button-hole type of opening, but a skin incision approximately four inches long Mont R Reid⁹ in a recent article states that a study of over 2,000 cases of acute appendicitis operated at the Cincinnati General Hospital shows that there has been a decrease of 50.3 per cent in the mortality rate since the operative procedure was changed from a rectus to a McBurney incision

If unexpected complications require more exposure the McBurney incision is easily extended in any direction to give access to any pathology in the right half of the abdomen In a recent case of acute appendicitis we found that the primary obstruction of the appendix was caused by a carcinoma at the junction of the appendix and cecum By extending the outer end of the incision upward and the inner end downward, we had an excellent exposure for the radical removal of the cecum, ascending colon, and proximal portion of the transverse colon The peritoneal vaccination furnished by the acutely inflamed appendix was the best possible insurance against peritonitis and we unhesitatingly closed without drainage

REMOVAL OF APPENDIX

If the appendix is free it is removed by the simplest possible method After ligation of the mesoappendix the stump is doubly ligated with chromic gut, divided and sterilized with the cautery and dropped back into the abdomen The wound is closed without drainage unless the appendix is grossly gangrenous, when the superficial wound is drained

The stump is never crushed because there is no reason for devitalizing it A purse-string suture is not only useless but potentially harmful because always infected It is never employed unless infection of the base of the appendix or the adjacent cecal wall constitutes a danger of fistula Adhesions do not form on a ligated dead stump but they are invited by an infected suture in the wall of the bowel

If adhesions surrounding the appendix render it difficult to expose the tip, the

base is found by following the longitudinal band and the base is ligated and divided between the ligature and a clamp. By retrograde dissection such an appendix can often be removed without disturbing the adhesions or breaking through the protecting wall.

Retrocecal appendices are best exposed and delivered by incising the outer leaf of the mesocecum and rolling the cecum inward.

DRAINAGE

We cannot too strongly emphasize the vital importance of understanding when drainage is necessary. Indiscriminate omission of drains would only add to the tragedies of appendicitis already so prevalent in this country.

Whenever infection of retroperitoneal tissue occurs, either from perforation or from a gangrenous appendix, wide-open drainage is essential.

In the presence of diffuse peritonitis, with purulent fluid seeping into view between non-adherent loops of bowel, removal of the appendix and closure of the peritoneum without drainage is indicated. In such cases, suction with a Pool suction tube should be used to remove as much as possible of the infected fluid. The muscles may be loosely closed, but the skin and subcutaneous tissues are better left wide open and packed with B. I. P. gauze, which is not disturbed for four days. When it is removed the wound is usually clean and may be closed. If the aponeurosis is gray and necrotic, a wet pack of Dakin's solution or Eusol, changed frequently, should be used.

Between these two extremes is found the large number of cases where surgical judgment is so important. Take for example a patient in whom the opening of the peritoneum is followed by a flow of pus either thick and "laudable" or thin, stinking, and deadly. The appendix may be perforated or merely gangrenous. The pus may occupy a small cavity surrounding the appendix with walls formed by fresh agglutinating adhesions, or it may fill the right side of the abdomen or the pelvis. Usually there will be extensive deposits of fibrin. What is the proper procedure?

With utmost gentleness the appendix is sought and removed. No packs are used, but a few moist gauze sponges may be necessary to hold back intruding loops of bowel. The pus is aspirated. If the

peritoneum is smooth everywhere and there is no bleeding, the peritoneum should be closed. If hemostasis is not complete or if any part of the abscess wall appears gray, shaggy, or necrotic, a soft cigarette drain should be inserted, or the cavity if small should be loosely packed with gauze. The peritoneum and muscles must not be sutured tightly about the drain. After twenty-four to forty-eight hours, the drain should be partly withdrawn or entirely removed, because at that time it is acting merely as a cork.

Advocates of the Ocshner treatment argue that it is bad practice to operate after peritonitis begins and before the infection is walled off because of the danger of spreading the infection. On the contrary, the early removal of a ruptured appendix is the surest way to stop the spread of peritonitis. Buchbinder¹⁰ referring to the experiments described above says:

I believe that what I was able to demonstrate in this series of cases was the importance of invading the peritoneum in the presence of spreading peritonitis when the removal of a septic process was possible. I believe furthermore that this series demonstrated not only the inefficacy of drains . . . but also the danger, since control animals . . . in whom drains were inserted, almost uniformly died. Autopsies on the latter group indicated that the drains produced a further spread of the infection.

Adhesions are permanent only when formed around a foreign body or around a focus of infection which is not removed before the fibrin becomes organized. With early removal of the source of infection and in the absence of drains fibrinous adhesions usually disappear completely in four or five days.

The limits of this paper forbid a discussion of other types of peritonitis. It suffices to say that few if any infections are more virulent than those from a perforated appendix. We have closed without drainage forty-eight consecutive cases of acute salpingitis or tubo-ovarian abscess with no deaths and no serious complications.

SUMMARY

1. It has been shown to be impossible to drain the general peritoneal cavity by any means whatsoever.

2. In the absence of catharsis infection rarely reaches all parts of the peritoneum before being walled off. Truly generalized peritonitis is comparatively rare and usually fatal. (Cf. Buchbinder.¹¹)

3 Death from peritonitis *per se* without operation is almost always death from overwhelming toxæmia. Intestinal paralysis and stasis are not important factors. On the contrary after operation with drainage ilcus is probably the most frequent cause of death. (Cf Steinberg¹²)

4 In all types of peritonitis except tuberculosis, early removal of the source of infection should be and usually can be effected.

5 Purulent and badly contaminated fluid exudates should be removed, preferably with a Pool suction tube, to lessen absorption.

6 The subperitoneal tissues are no more resistant to infection than are connective tissues elsewhere. Endothelium must be preserved by avoidance of rough sponging and dry packs.

7 Drainage is necessary in (a) Retroperitoneal infections, (b) localized abscess with doubtful integrity of the peritoneal lining, (c) peritonitis with uncontrollable oozing of blood.

8 The more widespread the peritonitis the less the indication for drains.

9 The skin incision should be left wide open and loosely packed with B I P gauze until subcutaneous fat and fascia appear clean. If muscles are sutured, interrupted sutures loosely tied should be used with drain to preperitoneal space.

10 Fever after forty-eight hours is usually due to infection of the abdominal wall. If an intra-abdominal residual abscess forms it should be allowed to localize and become palpable before being drained.

11 It is demonstrated that non-drainage reduces the danger of postoperative obstruction, perforations and adhesions. It gives a lower mortality, lessens suffering and shortens convalescence.

*LOCAL BOY MAKES GOOD IN A BIG WAY

This traditional headline of the country paper seems to apply to a son of up state New York. He is Dr Sylvester Maxwell Lambert, of Ellenville, who now has a practice of some 1,000,000 patients in 8,000,000 square miles of sea and land in the Pacific Ocean. As related in the *American Magazine*, he is director of the medical work of the Rockefeller Foundation in the islands of the Pacific Ocean—a roving commission with a variety of duties. Treatment by internal medicine and injections, of hookworm and yaws, two of the worst scourges of the tropics, comes first. Then he teaches the principles of hygiene and sanitation to the natives and assists the various island governments to co-ordinate their medical departments into one service.

Dr Lambert reports that the natives of the Pacific islands formerly reported dying out are now increasing. He said to Mr John W Van dercook, writer of the article.

Hookworm happens to be easily curable. It didn't used to be. In 1921 Dr Maurice C Hall, zoölogist of the Bureau of Animal Industry of the United States Department of Agriculture

found that a small dose of carbon tetrachloride, one of the cheapest, simplest things on earth (dry cleaners use it instead of gasoline), would clean out, at once, 90 per cent of a patient's hookworm parasites.

'Having something like that to peddle believe me makes travel easy. The work of the Foundation and the government—this health business is done on a partnership basis of course—did more to civilize Malaita I think than all the missionaries and punitive expeditions of fifty years.'

'I suppose you don't care a darn about the Native Medical School! But it's more important than all this stuff put together. It's the first of its kind in the world—a school where natives receive a full course in modern medicine so they can go back and teach their own people. It's located here in Suva.'

All the students are Pacific Island natives. Forty students are enrolled. In exchange for their tuition they must serve their own people. It's a tough job we're giving them—to apply modern medicine in some cases to people just emerging from the stone age. But these boys can do it.'

OBSERVATIONS ON SOME DISTURBANCES OF THE
VESTIBULAR FUNCTION

PAGE NORTHINGTON, M.D.

*From the Department of Otolaryngology, College of Physicians
and Surgeons, Columbia University, New York City*

The sufferer from vertigo has an apprehension and foreboding, not comparable to that caused by any other symptom. To him both the sun and earth do move. This sensation of motion not true to fact that we term vertigo, is the most distressing of the symptoms resulting from disturbances of the vestibular function. The accompanying nystagmus, and disequilibrium are usually proportionate in degree to the vertigo if the cause be located in the peripheral vestibular system—the eighth nerve or inner ear. Menière's disease is a very popular diagnosis in patients having vertigo, tinnitus, and impaired hearing. The possible exception here may be when these symptoms either are associated with a purulent ear infection or when they are post-traumatic. Although Menière was the first to relate the well-known group of symptoms producible by a lesion of the peripheral vestibular system, it is merely a syndrome and does not represent a disease entity. In fact, Menière's autopsy report on his patient leaves its reader in doubt as to whether the ear pathology present was from a hemorrhage or a labyrinthitis. It was probably the latter. Menière's syndrome, as has been suggested by others, is a more appropriate terminology because this group of symptoms may result from any one of several pathologic processes affecting the ear or eighth nerve. Impaired hearing, tinnitus, and vertigo, which represent both impaired cochlear and vestibular function, vary in their intensity not only with the amount of the loss of function but also in respect to the onset and course, whether a sudden ablation of function, a recurrent interference, or a slowly progressive loss is the case. For example: In a patient suffering from a fracture of the inner ear, the acute symptoms will be marked vertigo, with nausea and vomiting and falling to the side of the injured ear, nystagmus (quick component) to the side of the normal ear, and total loss of hearing on the injured side. When there is a recurrent interference of function—as may

be seen in toxic disturbances of the labyrinth—the patient has attacks of vertigo of a slight to a severe degree, with intervals of comparative well-being. Tinnitus and impairment of hearing may be present in such cases. In a slowly progressive loss of eighth nerve function, such as may be produced by an acoustic neuroma, compensation for the vestibular loss usually keeps pace, and there may be very slight or no vertigo. Unilateral tinnitus and deafness are the more prominent symptoms in this type of case. Although Menière's syndrome, along with the findings on examination of impaired cochlear and vestibular function, signifies a peripheral disturbance—inner ear or eighth nerve intracranially—a correlation of the history, findings on testing, and neurological examination may be necessary to determine whether or not the primary pathologic process is peripheral or central, since one may be a complication of the other. As may be found on functional ear examination, signs pointing to a central lesion in the presence of a purulent middle ear infection or an acoustic neuroma, or on the other hand, a cerebellar tumor may involve the eighth nerve resulting in signs indicating a peripheral disturbance.

It should be noted here that a bilateral loss of vestibular function of an equal degree does not cause symptoms representing the sum of the two unilateral losses but rather an entirely different symptomatology from that of a unilateral loss. There is no vertigo and no nystagmus. Inability to maintain correct station and gait will be found which is more pronounced either on abolishing the aid of vision in maintaining equilibrium or certain afferent sensations when in the stable mediums of air or water. The disequilibratory disturbance here is permanent. Bilateral total loss of eighth nerve function is more usually seen in children as a complication of meningococcus meningitis and in adults due to syphilis. The otologist is in a position to render a very helpful service in the case

of children with deafness following meningitis. It is usually impossible to determine solely by cochlear tests, whether or not there is any hearing present in these young patients. On the other hand, if the vestibular tests be used and show a complete loss of function, the cochlear function is almost certainly lost. The futility of any treatment directed toward restoring the hearing should be told to the parents and they should be advised as to the proper schooling so that the afflicted one may have a chance for social adjustment.

When the vestibular system is involved centrally, there is no definite group of symptoms comparable to that of Meniere's syndrome found in peripheral disturbances, on which to depend for aid in diagnosis. In central lesions of the vestibular system therefore, the examination becomes merely a determination of the functional reactivity of the eighth nerve to the tests, and the findings must be correlated with those of the general neurological investigation of the patient.

Certain variations of the eye movements from the normal which may be either spontaneous or reactions brought out in the tests are dependable manifestations of a central vestibular disturbance, whereas the vertigo present and the degree and type of past pointing and falling may be only confirmatory evidence of the results of the general neurological findings that indicated a brain lesion. A spontaneous nystagmus other than a horizontal-rotary type is almost invariably of central origin, if a small group that are found in eye disorders are excluded. Even when the nystagmus is horizontal rotary in type and the direction (quick component) is to the side of a known ear lesion, it is usually of central origin. The usual description of nystagmus in a labyrinthitis, namely, that the direction of the nystagmus is first to the side of the infected ear, caused by irritation, and later to the opposite side when the labyrinthitis is fully developed, has not been my observation. I have never seen a nystagmus, present in the primary position of the eyes, with its direction to the side of an uncomplicated ear infection, and only once to the side of an ear injury. In this case, there was a basal fracture involving the ear and, of course, the nystagmus may not have been caused by the ear lesion. If on rotation or caloric tests, a nystagmus is induced that varies qualitatively with the normal type of re-

sponse, a central disturbance is definitely the cause. These qualitative variations may be either a perverted or an inverted type of nystagmus, either dissociated eye movements or a conjugate deviation of the eyes. I am of the opinion that these abnormal reactions, result from some interference in the vestibulo-ocular pathways, from the vestibular nuclei to the motor oculi nuclei inclusive. This disturbance of the vestibulo-ocular reflex may be due to a lesion which primarily involves that area of the brain or secondarily from pressure produced by an expanding lesion in some other brain region. As to conjugate eye movements, that is, the slow component of the nystagmus being present and the quick component absent on vestibular tests, neither clinical nor experimental observations have provided conclusive proof of the cause other than that there is a central lesion involving the vestibulo-ocular pathways. I have seen conjugate eye movements occur on vestibular tests, away from the side of a brain stem lesion and, also, to the same side of a cerebral tumor. In the Department of Neuropathology, New York Psychiatric Institute, Doctor Barrera and I are at present carrying out some investigations on the vestibular mechanism in the monkey which we hope will provide some information on the quick component of nystagmus.

The degree of vertigo induced by the tests will vary considerably in normal persons and the past pointing is usually proportionate to the vertigo. Although a wide latitude is allowed for the normal limits, at times certain inconsistencies in the vertigo and past pointing will be present that at the least are confirmatory of pathology of the central nervous system. It has been reported by many authors, and my observations confirm theirs, that in the presence of an expanding lesion of the posterior fossa the patient has very little or no vertigo and past pointing on vestibular testing. Normal persons may likewise be quite tolerant in this respect. The greatest usefulness, therefore, of this observation, as an aid in diagnosis is when the neurological examination reveals signs of an expanding intracranial lesion without definite evidence of a supra- or subtentorial location. In such an event, if the patient develops marked vertigo with nausea and vomiting on testing, it is almost certain that the lesion is supratentorially located.

Nausea, Vomiting

Instead of attempting a more detailed report of the disturbances of the vestibular function, it seems more profitable to cite a few illustrative cases. In these case reports, there are recorded only the relevant facts in the history and examination of each patient. In most of the cases the functional examination charts are shown as the findings are more easily followed than if only given in the text.

CASE I.—Woman, age 25 years, admitted to Presbyterian Hospital with symptoms of a right acute mastoiditis; no complications. It was a recurrent ear infection. A polyp protruding through a perforation in the drum membrane was removed and instantly the patient suffered of marked vertigo, nausea, and vomiting. On examining her four hours later she was lying on the left side; that is, the diseased ear was upward, the most comfortable position to assume in such a vestibular disturbance. A horizontal-rotary nystagmus present was to her left side, and falling and past pointing was to her right. She could hear whispered voice in the right ear. The patient was too ill for a complete functional examination of the ears. The presence of hearing warranted the opinion that the patient had not developed a purulent labyrinthitis and that she should be observed, without having any operation at the present time. The vestibular symptoms subsided and ten days later, a simple mastoidectomy was performed. Two months later the cochlear and vestibular reactions were within normal limits. This chart is shown in order to demonstrate the procedure followed in the tests and the average findings in a normal case.

CASE VII.—Man, age 34 years. Dizzy attacks, deafness, and noises in the right ear for five weeks. Recurrent drainage from the right ear for ten years.

Vestibular reactions showed poor past pointing and a vertical nystagmus upward in the face-up position on caloric testing of the right ear. This qualitative variation in the nystagmus reaction indicates brain stem pathology, either as a direct involvement or through pressure. The hearing was slightly impaired on the right side. There was a small foul discharge coming from a marginal perforation in the attic region of the right ear. Roentgen ray examination of the mastoids showed the right to be sclerosed. A neurological examination at this time did not reveal any evidence of a focal lesion in the brain. Two days later, however, a neurological examination gave the impression of a right temporal lobe abscess. A lumbar puncture was done at this time. The spinal fluid was under pressure and the cell count was 50 lymphocytes. The patient died a few hours later, presumably from the result of the lumbar puncture. The evidence here suggests the presence of a brain abscess.

Menière's syndrome occurring along with a purulent middle ear infection usually indicates a pathologic process that requires an ear operation, especially when the ear infection is of long standing. Although otologists may not agree on the method of handling such cases, the opinion in a given

patient must be based on the inner ear condition as determined by the evaluation of the history, physical examination, and functional disturbances—spontaneous and that brought out on the cochlear and vestibular tests.

CASE III.—Man, age 38 years. He had spells of dizziness, with nausea and vomiting for nine months, and progressive loss of hearing and tinnitus in the right ear for fifteen years. There was no history of an ear infection.

Vestibular reactions to temperature were slightly impaired on the right side. Hearing was impaired in both ears, greater in the right; perception type. A general neurological investigation did not reveal any organic disease. Ears appeared to be normal. Tonsils were moderately injected. Adenoids, moderate size, were present, larger in the right Rosenmüller fossa. The right eustachian tube was slightly obstructed. His condition improved on inflations of the right ear. After tonsillectomy and adenoidectomy, he was relieved of the vertigo and his hearing improved.

It is not customary to get so much improvement of hearing in such patients as is noted here, even when the vestibular disturbance subsides.

CASE IV.—P. H., 392,159, woman, age 25 years. She was admitted to Presbyterian Hospital a few hours following a severe head injury. Marked vertigo, nausea, and vomiting were her chief complaint. Examination showed a nystagmus to the left, blood in the right ear canal, and very good hearing for whispered voice. Although she had a basal fracture involving the ear, the good hearing present would assure one that the fracture did not include the inner ear, and that the prognosis for complete recovery of cochlear and vestibular function was good. Three months later the functional ear examination showed normal cochlear and vestibular reactions. The vertigo and nystagmus had subsided.

CASE VIII.—Woman, age 28 years. She complained of noises and impaired hearing in the right ear; giddy feeling at times with faulty gait. Her symptoms followed a head injury a year ago, in which she was unconscious for several hours. She had a basal fracture. There was no bleeding from the ears. Since the accident, this patient had received ear inflations. Tonsillectomy and adenoidectomy had been advised as treatment for the right ear deafness. The ears appeared to be normal.

Functional ear examination showed a total loss of vestibular and cochlear function. The history along with a total loss of vestibular function precludes, of course, any chance of restoring the hearing.

Cases IV and VIII illustrate that basal fractures involving the ear may or may not have bleeding in the external ear canal. Also, that irreparable loss of ear function may be present when there is no bleeding and, therefore, the bleeding from an ear in a head injury is not dependable as evidence of the extent of the damage and functional loss.

CASE XI.—P. H., 78,598, woman, age 35 years, admitted to Presbyterian Hospital, with the complaint of dizziness with nausea and vomiting, deafness and "roaring" in the right ear. The onset was sudden, four days previously, at which time an ambulance surgeon was called and prescribed soda bicarbonate for the stomach upset. When I saw her she was lying on her left side, a horizontal-rotary nystagmus to the left was present and impairment of hearing to voice testing of the right ear. She was too uncomfortable to attempt a complete functional ear examination at this time. There was no history of an ear infection. Her ears, nose, and throat appeared to be normal. Vertigo became less and after two weeks she was able to carry on with very slight discomfort. The tinnitus and deafness remained as on admission. A functional ear examination, one month after the onset of the symptoms, showed a marked impairment of hearing in the right ear chiefly in the *lower tones* and a slight impairment of vestibular function on the right side. A recent functional examination, six months later, showed almost identical findings as noted above. However, there was no vertigo and only slight ear noises. During this patient's stay in the hospital, a complete investigation of her condition was carried out. Nothing additional to the history and findings related above was discovered to aid us in a diagnosis. The onset, course, and findings here suggest a vascular lesion of the right inner ear. A speculative diagnosis is: an occluding process of the division of the labyrinthine artery (Shambaugh) which supplies the upper portion of the cochlea and a part of the vestibular end organ.

CASE X.—N. I., 10,307, woman, age 30 years, admitted to the Neurological Institute complaining of tinnitus and loss of hearing in the right ear for three years. No vertigo at any time during the three years. She had been treated by four otologists. There was no history of a middle ear infection. She had received inflations of the eustachian tube, treatment for sinusitis, and electrotherapy. There had been no relief of her symptoms.

A neurological examination just prior to the functional ear examination recorded here, revealed evidence suggesting a right eighth nerve tumor. Hearing was greatly impaired in the right ear. Vestibular reactions were absent on the right side and impaired on the left. The cochlear and vestibular impairment here confirmed the diagnosis of an eighth nerve tumor. The examination of this patient illustrates the lack of dependability of the rotation tests in revealing unilateral vestibular loss in eighth nerve tumors.

A record of the audiometric test and rotation test which were done two and a half years ago was available and showed findings almost identical with those shown here. No caloric test was done at that time. It is a fair assumption that a caloric test on the initial examination, two and a half years ago, would have given evidence of sufficient vestibular impairment on the right side which along with the cochlear loss would have prompted a neurological investigation of this patient's condition.

We should bear in mind that the early subjective disturbances of eighth nerve tumors are almost invariably deafness,

tinnitus, and vertiginous attacks. The vertigo may be very slight or entirely absent as in this case. From the onset of symptoms, before other structures in the posterior fossa than the eighth nerve are involved to the extent of giving subjective symptoms, it may be a duration of years. The early manifestations of eighth nerve tumors suggest an ear disease to the sufferer. Relief is sought from the otologist as shown in the histories of all such patients examined by me. But rarely has the cause of the ear symptoms been suspected by the otologist until other neurological signs developed. It is believed that a complete functional ear examination should be done in all patients having a unilateral loss of hearing, and tinnitus, with or without vertigo, unless these symptoms can readily be accounted for by a middle ear disease. A total loss of vestibular function and a moderate loss of cochlear function on one side, along with a suggestive history, is sufficient evidence of the presence of an eighth nerve tumor to warrant a thorough neurological investigation of the patient's condition.

CASE IX.—P. H., 225,777, man, age 40 years. He had recurrent severe vertiginous attacks in which he would fall on the street. There was deafness in the left ear and the sound of "steam escaping." The ears appeared to be normal and there was no history of an ear infection. There was moderate impairment of vestibular and cochlear function, perception type, on the left side.

The general neurological investigation resulted in the opinion that this patient suffered from a left eighth nerve tumor. On operation a left cerebellar lobe tumor was found. There was not sufficient loss of cochlear and vestibular function in this patient to suggest an eighth nerve tumor. I have never seen a proven case of eighth nerve tumor in which any vestibular reaction was shown by the tests on the side of the lesion.

CASE XII.—Brain tumor, 74, B. H., man, age 47 years. Admitted to Bellevue Hospital complaining of frontal headaches, vomiting, and impaired vision.

The neurological diagnosis was tumor in the right temporo-occipital area, deep. Autopsy findings confirmed this diagnosis. The hearing seemed to be normal in this patient. The vestibular reactions showed definite signs of a central lesion in any one of the following findings: conjugate deviation of the eyes, dissociated eye movements, and perverted nystagmus. The nausea and vomiting due to the testing was decidedly against a tumor in the posterior fossa. The conjugate deviation of the eyes to the right along with signs of a supratentorial tumor suggested a right cerebral tumor.

ABSTRACT OF DISCUSSION

DR. RICHARD M. BRICKNER, NEW YORK: While I am not competent to discuss Dr. North-

ington's paper from the technical standpoint of an otologist, the author has emphasized a number of matters which are important from a neurological point of view.

The fact that "Menière's disease" is merely a syndrome and not a disease entity is especially vital to the neurologist. The term "Menière's disease" is one of a fairly large group which has probably led to unnecessary deaths, because of the strong tendency to consider that, when a name has been given to the patient's condition, the matter is closed. It is of primary importance to escape from the tendency to consider the question answered by giving it the name "Menière's disease." Only by doing so is it possible to isolate, from the mass of vertigos and tinnitus, those cases in which early removal of a cerebellopontine angle tumor may save the patient's life.

As Dr. Northington indicated, there are other forms of operable intracranial tumor which may produce vertigo, tinnitus, and deafness—those of the hemispheres of cerebellum, which compress the eighth nerve, and also cysts of the arachnoid in the cerebellopontine angle, the drainage of which may result in grateful relief. In addition, tumors of the cerebral hemispheres themselves are often associated with vestibular and cochlear symptoms. These may result from direct pressure upon the eighth nerve, a phenomenon which sometimes occurs when the tumor grows inward and downward from the medial side of the temporal lobe. But such symptoms need not necessarily depend upon direct pressure; some of them may be the result of the generalized increase in intracranial pressure, with a corollary blocking of the flow of endolymph in the structures of the internal ear. It is even possible that deformities of the brain stem, resulting from the stresses and strains of increased intracranial pressure, may produce these otologic symptoms, either by interference with the central pathways, or possibly through compression of the eighth nerve by the internal auditory and anterior inferior cerebellar arteries. It is also always to be remembered that the deafness may have some other, irrelevant, cause. In all of these situations, operation may result in cure, and it is of the utmost importance to avoid the dangers of casual diagnosis. No case of vertigo or tinnitus should be considered properly studied without a neurological examination. Similarly, no patient who has these symptoms, and who actually shows neurological changes, can be thought of as completely investigated unless rotation and especially caloric tests have been done. While the vestibular tests are not necessarily the final word in the study of the patient, they are often of great importance in helping us to determine what portion of the cranial cavity contains the tumor.

Probably their greatest usefulness in this particular respect lies in the exclusion of tumors of the eighth nerve. It is by no means rare to have a patient with a low-grade papilledema, whose chief symptoms are vertigo, tinnitus, and deafness, and who is thought of as having an acoustic neuroma. When tests show that the function of the vestibular nerve is relatively intact, it is, as Dr. Northington has pointed out, very definite evidence that the tumor is located elsewhere, probably supratentorially. At the Neurological Institute, considerable dependence is placed particularly upon this phase of the matter. Apropos of eighth nerve tumors, it should be emphasized

that bilaterality of involvement of the vestibular nerves does necessarily point against this diagnosis. In fact, such a tumor, if it grows to any size, is very likely to compress the brain stem sufficiently to produce changes in the vestibular and cochlear nuclei and central pathways, so that the impairment of the function must be bilateral. This is exemplified in Dr. Northington's tenth case. Incidentally, tumors of the eighth nerve do not, as is often thought, always produce facial paralysis. The facial nerve is peculiarly resistant to pressure, and there is frequently no disturbance in its function.

Another very important field in which the vestibular tests may be vitally important, is that of psychogenic disturbance. The differentiation between organic and psychogenic symptoms is admittedly one of the most difficult in medicine; this is particularly true in neurology, because there is no psychogenic symptom referable to the head which cannot also be produced organically. The fact that a neurotic personality affords the background for neurotic head symptoms may confuse the picture more than help it, because neurotics may, of course, also develop brain tumors. Among the most frequent psychogenic symptoms are vertigo and tinnitus. At the Neurological Institute, practically all patients with these symptoms are subjected to the vestibular tests, even when a psychoneurosis is the probable basis. When, under these circumstances, the tests show definitely normal vestibular function, the help obtained is of a very reassuring nature. When, as happens occasionally, Dr. Northington is able to demonstrate physical change in the vestibular pathways, the change in viewpoint may be life-saving.

Dr. Northington's Case IX, in which the impairment of the vestibular reactions was too small in degree to warrant the diagnosis of eighth nerve tumor, is of considerable interest. Though the history and neurological examination indicated the presence of such a tumor, the neoplasm was found in the left cerebellar hemisphere. This case illustrates the degree of accuracy which may be achieved by the vestibular tests. Such accuracy is of special importance in tumors of the posterior fossa, where the other great aid of neurology, encephalography, is dangerous.

DR. BASSERA: Dr. Northington mentioned the fact that he and I have been studying vestibular functions in monkeys at the Psychiatric Institute. We thought that it might be of interest to you if we occupied a few minutes of your time by telling you something about this investigation.

It has been our good fortune that Dr. Ferraro in his Department of Neuropathology at the New York State Psychiatric Institute and Hospital inaugurated some three years ago an intensive program of experimental investigation of the central nervous system in monkeys, a work which has been consistently supported and encouraged by Dr. Clarence Cheney, Director of the Institute.

Since the work was first started, Dr. Ferraro and I have operated upon, and studied, over 200 monkeys in which various experimental lesions of the central nervous system had been performed. The lesions were of all types, including partial and complete removal of the cortex, lesions of the midbrain, lesions of various portions of the dorsal-column system, and finally in what has formed the major portion of our work, lesions of the cerebellum in its various portions including isolated and combined sections of the various

peduncles and partial and complete removal of various portions of the cerebellum.

In addition, we have studied the effects of lesions of the central vestibular apparatus including the nuclei, the vestibulocerebellar and the

and I have studied the effects of lesions of the inner ear and of the eighth nerve. In all of these animals we have studied responses of the animal to the various vestibular tests including the rotation, caloric, and galvanic tests. We used a chart somewhat similar to that used in human cases. We have been particularly interested in the modification in the nystagmus responses associated with the various lesions, and in some of the grosser lesions we have been interested in the question as to the origin of the quick component. These results will all be tabulated against the histological findings as studied by Dr Ferraro and myself and should prove of decided interest. One of the major deficiencies in human clinical work has been, with rare exceptions, the absence of fine anatomical control to associate with clinical vestibular findings. This, we feel, will not be the case in our present series because each brain which has been subjected to an experimental lesion is studied completely in serial section so as to have a definite unequivocal tabulation of the exact structures involved in the lesion. This is one of the factors requiring so much time for the completion of the work. We feel, however, that the expenditure of time is well justified, as, when it is finished we expect to have systematic vestibular observations under controlled anatomical conditions of a large series of monkeys which we hope may lead us to a better understanding of the functioning of the various components affecting the nystagmus response originating in the various portions of the brain.

DR KARL GRUPP, *Utica*. The labyrinthine system, which I believe is admirably named, has so far foiled the attempts of neuro-anatomists to arrive at a complete understanding of its interconnections and hence the frequent lack of correlation of signs and pathology is not so surprising. Progress is being made, however, and new

concepts will be held. The work of Magnus, for instance, has assailed the old established conception of the quick nystagmus component being of cerebral origin and Ginkler of Chicago in his recent Textbook of Neurology accepts the vestibular rather than the cerebral origin of the quick component, or at least seriously questions the latter.

It is rather in central than peripheral disease that conflict occurs. The literature contains reports of many authors who claim that some definite localizing aid is to be derived from careful study of nystagmus but again these reports are usually terminated by listing exceptions. Gordon Holmes, however, did find fairly consistent eye signs in his excellent study of cerebellar war wounds.

My own conclusions based on discussions, observation and a study of case histories are as follows: (1) Atypical responses to stimulation indicate some central disturbance. (2) A coarse, floppy spontaneous nystagmus usually means disease somewhere in the cerebellum provided no eye disease is present. (3) Vertical nystagmus may indicate disease of the upper brain stem. (4) In nystagmus of central origin the point of fixation usually determines the direction of the quick component in contrast to the fixed direction of vestibular nystagmus. (5) The direction of falling in cerebellar disease is irregular in contrast to that of vestibular disease which definitely follows the position of the head. (6) Cases in which atypical vestibular signs and symptoms are present without other evidence of intracranial or ear disease may be on a toxic basis, in which connection I cite a case of yatrien poisoning used in treatment of colitis, during which one observer detected a vertical nystagmus.

Dr Northington's case histories are interesting. I think that his first case illustrates pretty well the dangers lurking behind each aural polyp, and that its removal by snare or forceps may usher in the last act. Case III with its clearing of vertigo and improvement of deafness following T and A was a revelation and I would like to ask Dr Northington if he considered the effect a mechanical one or rather removal of focus of infection.

INSTEAD OF NEW CANCER CURES

We should cease worrying about finding a new cure for cancer, remarks Dr J. Shelton Horsley, in the *Bulletin of the American Society for the Control of Cancer*, for the study of the biology of cancer appears to show that constitutional remedies or serums will probably never be effective. The important thing in the treatment of cancer is not to search for new cures, but to search for new methods of early diagnosis so that the efficient well known cures can be promptly applied. Unfortunately, except in the case of bone tumors, cancer does not cause pain in the early stages, so we shall have to fall back upon the teaching of the late Sir James MacKenzie, and emphasize the observation of disease

in its incipency and a careful and thorough study of what seem to be casual symptoms, as the indigestion, belching, heartburn in cancer of the stomach and bowel, the slightest irregularity in contour or substance of the breasts, or any unusual appearance on the skin or mucous membrane in any portion of the body. These signs or symptoms usually appear before the later symptoms of loss of weight, bleeding, ulceration or marked abnormal discharge. If we study more thoroughly things that appear to be casual and trivial in the beginning of the disease, and consequently make an earlier diagnosis, cured cases of cancer will increase enormously.

CHEMISTRY IN THE MEDICOLEGAL AUTOPSY

ALEXANDER O. GETTLER, Ph.D.

From the Chemical Laboratories of the Chief Medical Examiner's Office, Bellevue Hospital, and of Washington Square College, New York University, New York City

Chemical methods when applied to autopsy material are extremely intricate; and at the same time great responsibility is involved. How phosphorus or strychnine is detected every chemist knows, but to isolate and detect 1/100 of a milligram (1/6000 of a grain) of strychnine present in 500 grams of tissue is an entirely different problem.

Much experience is necessary. The person to whom the chemical analysis is entrusted should be a chemist with years of experience in autopsy material—accurate, honest, and trustworthy; his integrity of the highest and indeed above the remotest suspicion, due to the fact that his findings may be the basis for the acquittal of the innocent or the conviction of the guilty.

The toxicological experience in the chief medical examiner's office in New York City is the largest in the world, not overlooking the medicolegal institutes of Germany, Austria, and France. Annually in this office there are analyzed over 2,000 human bodies. Since the inception in 1918 of the chief medical examiner's office in New York City, over 25,000 human bodies have been analyzed for poisons.

In the United States we have only two localities in which toxicological work is done as a routine, namely, New York City and Newark, New Jersey. In other cities and counties throughout the country no toxicological work is done as a routine. While writing this paper the author was called by long distance about a case that was troubling the authorities in a southern town. A man was driving along a country road in an open automobile. Witnesses saw the car swerve off the road and stop. The driver was found dead. The coroner, without any scientific investigation, signed it out as a carbon monoxide case. Doctors who had treated this man for the past few years claimed that they had advised him not to take this trip because of heart trouble. Instead of proving the presence or absence of carbon monoxide in the blood of the deceased by accurate chemical methods, the officials tried to argue the point whether the man had died of carbon

monoxide poisoning or of natural causes. Most of the cases throughout the country are malhandled in this way.

Cases appear that receive much notoriety in the newspapers. Then the officials seek the services of so-called experts. Upon investigation one can usually find that these so-called experts are but novices in toxicology. This condition exists throughout the country and it was the condition in New York City before 1918. The experts engaged in the Rice Case cost New York City \$30,000 for argumentative proof of whether Rice died from the effect of chloroform or not. No analysis for chloroform was made; it all depended upon which side produced the best argument. In the toxicological department of New York City a chloroform case of this kind would be completely solved in about two hours by a scientific chemical analysis. A rough estimate shows that the average cost to New York City for a complete toxicological examination, including grand jury and court testimony is \$5.00 per cadaver. In New York City to-day every case of accident, suicide, homicide, and most cases of sudden deaths with no medical attendants, are autopsied and chemically analyzed. A few of these cases will be described in order to point out the part played by toxicology in solving the cause of death.

1. ANALYSIS OF THE STOMACH CONTENTS THE MAIN, OR PERHAPS THE ONLY MARK OF IDENTIFICATION OF THE DECEASED. *The Becker Case.*—Becker, and his wife and two children lived in the Bronx, N. Y. Mrs. Becker suddenly disappeared. Letters mailed in Philadelphia to friends of Mrs. Becker stated that she was tired of living with her husband and therefore she had gone to Philadelphia, that she was well, and not to worry any further about her. Her friends, however, did not believe these letters. They knew, although she might have left her husband, that she loved her children too well to leave them behind. Mrs. Becker's friends therefore brought the matter to the attention of the District Attorney.

Investigation was started by the police. Mrs. Becker could not be found anywhere. After a few weeks of good detective work a clue was unearthed that Mrs. Becker had been buried in the yard behind a garage owned by a friend of Becker. The police proceeded to search for the body in this yard. After quite some digging, they found the body of a woman, completely covered with lye. The clothes, the face, and most of the external parts of the body were well chewed up by the lye so that it was impossible to identify the woman.

The body was autopsied and chemically analyzed. The head revealed that the woman's skull had been fractured by a blunt instrument. No poisons were found. The stomach contents revealed grapes, figs, and nuts.

Meanwhile the detectives sought the person who had last seen Mrs. Becker alive. They found this to be a woman friend of the Beckers. She stated that Becker and his wife visited her about 10 o'clock this particular evening. When asked what they had eaten at her home, she told them, without knowledge of the chemical findings, that she had given them grapes, figs, and nuts. It was mainly upon the finding of these particles of grapes, figs, and nuts in the stomach of the deceased, that the State succeeded in the identification of the body as that of Mrs. Becker.

The Beckers left the house of their friend about 11:30 P.M. They got into Becker's taxicab and started for home. On the way Becker feigned engine trouble and drove into aforesaid yard. He got out and lifted the hood. He called his wife to come out of the car and see for herself. As she stooped he hit her over the head with a blunt instrument knocking her unconscious. He then threw her into a previously dug hole, covered her with lye and buried her. He was tried, convicted, and paid the penalty.

2. A CAMOUFLAGED POISONING CASE.—

An automobile was found burning in an out-of-the-way country road. The owner, also in flames, was lying across the front mud guard, dead. A case of this description would have been signed out by most coroners as one where death was due to accidental burning. The medical examiner's office, however, investigated. An autopsy was performed, and a toxicological analysis was made. It was found by scientific methods of analysis that the man

had not died of the fire, fumes or smoke. He was dead when the fire reached him. Further analysis revealed large amounts of cyanide in all his organs. Death was due to cyanide poisoning.

The case was solved as follows: The man had suffered great financial losses. He was practically penniless. He had a family, and he wanted to provide for them. He had taken out a large insurance policy with double indemnity in case of accident. His intention was to commit suicide, and at the same time make it appear as an accidental death, in order to get the double indemnity.

He put the car on fire, and when it was burning well, he drank the solution of cyanide. He then threw the container of cyanide into nearby shrubbery and fell dead over the front mud guard. Thus a case which had the appearance of accidental death by fire was one of suicide by cyanide.

3. CASE THAT APPEARED TO BE SUICIDAL GAS POISONING WAS PROVEN TO BE MURDER BY SUFFOCATION. *The Freindlich Case.*—

Freindlich, wife, and three children, 9, 7, and 2 years old—lived in a New York East Side tenement. On the particular morning in question the father left the home about 7 A.M. About 7:30 A.M. one of the boys noticed the odor of gas. He ran into his mother's room and found her in bed. He shook her, but she did not respond. The boy called for help. The neighbors called the police who in turn notified the medical examiner's office. On arrival of the medical examiner he found the room filled with illuminating gas. The gas jet was open. The woman was dead in bed, lying on her back in a natural position. There was no pink coloration of the skin of her face, or any other part of her body (as is usual with carbon monoxide deaths). Lying in a crib a few yards away was the two-year-old baby, still alive. The baby was quickly removed to fresh air and saved. The absence of pink coloration of skin of the woman, and the fact that the baby was still alive and the mother dead, made the medical examiner suspicious, and an autopsy was performed.

The toxicological analysis of the blood removed from the heart of the deceased mother showed complete absence of any carbon monoxide. This indicated that death was not due to inhalation of illuminating gas. The autopsy further showed

that death was due to suffocation. Ten finger marks of compression were found on the back of her neck.

Freindlich murdered his wife for insurance money. He held her face against the pillow until she was dead. He then turned her on her back, straightened out all of the bed sheeting, turned on the gas and left the house. He was tried and convicted.

Coroners or inexperienced county physicians would most likely have signed the case out as suicide by inhaling gas, whereas it was murder by suffocation.

4. ALCOHOL THE CAUSE OF ACCIDENTS.—The toxicological laboratory of New York City analyzes the brain for alcohol quantitatively in all cases of fatal accidents, the purpose being to determine whether alcoholic intoxication was a contributory cause to the accident.

Research work on over 6,000 human brains and on spinal fluid and blood of living human alcoholics, and many series of experiments on dogs in which brains, blood, and spinal fluid were analyzed, proved that if the alcoholic content of the brain or of the spinal fluid reaches above 0.25 per cent it indicates that the individual was intoxicated. This was found to be true whether the individual was an abstainer or a habitue.

Case of Famous Air Pilot.—This flier was one of the first who successfully crossed the Atlantic. Several years later he took off at Roosevelt Field with two male companions. Within a few minutes the plane crashed to earth and all three were killed. Examination of the wrecked plane revealed nothing as to the cause of the accident. The deceased pilot was autopsied and toxicologically analyzed. The results of the analysis indicated that the pilot was intoxicated at the time he took off; and evidently this condition of intoxication was the contributory cause of the fatal accident.

5. PLANTED BODY FOR PURPOSE OF COLLECTING INSURANCE.—This is the story of two undertakers that were partners in their business, in a rural community. One of the undertakers took out a large life insurance policy, with double indemnity for

death due to accident, and he made his partner the beneficiary.

Not many months later a bungalow that they owned was burned to the ground. The burned body of a man was found in the ruins. The undertaker who was the beneficiary claimed that this body was that of his partner, and he put in his claim for the insurance, asking for double indemnity because it was an accidental burning to death.

The insurance company started an investigation. An autopsy and a toxicological investigation was conducted. The results of the investigation were as follows:

1. The external part of the body was completely charred. The head was completely burned off. The feet and part of one leg were burned off. No identification was possible.

2. By measurement of the bones of the extremities that were left, it was estimated that the deceased had been about two inches taller than the missing undertaker.

3. Some parts of the internal organs were still in good shape; that is they were not burned or boiled. Examination of the lungs showed a well developed pneumonia while the undertaker in question was seen apparently in perfect health only two hours before the fire.

4. Toxicological analysis revealed no poisons, ruling out suicide by poison.

5. Toxicological work further revealed that the body found in the ruins was dead when the fire started. The fire or fumes or smoke had nothing to do with this man's death.

6. The toxicological analysis also revealed the presence of formaldehyde in the various organs. This strongly indicated that the body had been embalmed.

The case was fully solved. The body found was not that of the undertaker. It was a man two inches taller who had died of pneumonia, and had been embalmed for burial. This body the undertakers planted in the house, and then set fire to the house.

The six cases above outlined illustrate the nature of the work the toxicological department of the Chief Medical Examiner's Office of New York City is doing.

CUTANEOUS REACTIONS TO HEMOLYTIC STREPTOCOCCUS NUCLEO- PROTEIN IN RHEUMATIC AND IN NON-RHEUMATIC CHILDREN

ALBERT D. KAISER, M.D., and JOHN D. KEITH, M.D.

*From the Department of Pediatrics, the University of
Rochester School of Medicine and Dentistry, Rochester*

For some years rheumatic disease has been associated with a streptococcus infection but lately more clinical, epidemiological, and bacteriological evidence of the causal relationship of this micro-organism has been put forward. Though there is no unanimity as to the type of streptococcus associated with rheumatic disease, the conception of acute rheumatism as a manifestation of, or sequel to, infection with the hemolytic streptococcus has received much support. A new approach to a study of this relationship has been offered by intracutaneous skin testing with the products of the various streptococci.

Within the last decade numerous workers have studied the relation of skin reactions to filtrates and extracts of streptococci to rheumatism. The first of these were done using filtrates of the toxin; subsequently a dried-ground extract of the organism, referred to as streptococcus nucleoprotein, was used. It is not our purpose here to review the literature, but to set down some of the previous results for comparison with the present investigation.

In 1927 using a filtrate from a non-methemoglobin forming streptococcus Birkhaug¹ performed intradermal tests on 54 rheumatic children and a larger number of controls with a dilution of 1/100. Of the rheumatics 76 per cent were positive; of the non-rheumatics 13 per cent. In 1928 Kaiser,² using a similar filtrate in the same dilution, obtained 72 per cent positive among 90 rheumatic children and 20 per cent among non-rheumatic controls. In 1928 Irvine Jones³ made filtrates from a variety of organisms. That obtained from a hemolytic streptococcus was diluted to 1/500 and injected intradermally. Seventy-five rheumatic children were tested. Of these 30.86 per cent were positive, while 20.3 per cent of the control non-rheumatic group were positive.

Swift, Wilson, and Todd⁴ used filtrates of several non-hemolytic types of streptococci. These were described as giving just as strong reactions with boiled filtrates.

They found a higher incidence of skin hypersensitivity to this preparation in rheumatics than in non-rheumatics. Collis, Sheldon, and Hill⁵ suggest that Swift's preparation contained a considerable amount of the nucleoprotein or extract of the organism as well as toxin.

In 1931 Derick and Fulton⁷ prepared dilutions of nucleoprotein from a hemolytic streptococcus. The test was done using .1 c.c. which contained .001 mgm. nitrogen. Of the rheumatics 88.6 per cent gave positive skin reactions; of the non-rheumatics 12.3 per cent were positive.

Coburn⁶ in 1931 performed intradermal skin tests using a similar method of preparation from hemolytic streptococci with various dilutions for skin testing, but most frequently a dilution in which .1 c.c. contained .001 mgm. nitrogen. 99 per cent of his active rheumatics were positive; 36 per cent of his controls. 95 per cent of his patients who had had recent streptococcus infections gave positive skin tests to this material.

Collis, Sheldon, and Hill⁸ more recently tested 256 rheumatic children during active and inactive stages of their disease. Their skin-testing material was prepared from packed and dried hemolytic streptococci ground in a ball mill for a shorter period than that prepared by Coburn and by Derick and Fulton. They called it a hemolytic streptococcus extract. Two dilutions were made; in the one .1 c.c. contained .00005 mgm. nitrogen, in the other .00002 mgm. They found that approximately 80 per cent of rheumatic children were positive in the active stage. This was reduced to about 40 per cent at the end of one year. Grouped all together 58 per cent of the rheumatics were strongly positive, 17 per cent weakly positive, and 25 per cent negative. Of the controls 28 per cent were strongly positive, 19 per cent weakly positive, and 53 per cent negative.

Gibson, Thomson, and Stewart¹¹ used a similar extract, in which .2 c.c. contained .00028 mgm. They found 76 per cent of

the rheumatics positive, and 55 per cent of the controls.

In general, the reported studies reveal a high percentage of the rheumatic individuals positive to the filtrate or nucleoprotein of the hemolytic streptococcus. The variability of the results may be explained by the work of Ando, *et al.*⁹ who were able to demonstrate two factors present in toxin produced by culturing the streptococcus of scarlet fever; one a heat labile fraction which is destroyed by heating to 80° for 30 minutes, the other a heat stable fraction which cannot be destroyed by boiling for an hour. The filtrates used in the above mentioned investigations on rheumatic patients probably contained these fractions in varying proportions, depending on how long they were cultured. (It has been shown that there is some of the heat stable element present in the toxin after only 48 hours' culturing.) So the patients tested with the filtrates were receiving both materials. One may have been negative to the heat labile while giving a positive reaction to the heat stable portion of the skin testing material; or the reverse may have been true.

The purpose of this study was to determine the cutaneous reaction to the heat stable fraction of a hemolytic streptococcus. It is referred to as a nucleoprotein in the United States and called (H. S. E.) Hemolytic Streptococcus Extract in England. Over 800 children were utilized for these tests. The group included 200 known rheumatic children; a number with other diseases such as scarlet fever, tonsillitis, and respiratory diseases. There were also children tested before tonsillectomy was performed.

METHOD

A 48-hour culture in Douglas Broth of a hemolytic streptococcus (strain Q-33 obtained from a rheumatic patient, culture kindly sent us by Dr. Homer Swift) is made. Organisms are then centrifuged and washed and heated to 60° for one-half hour. Then they are frozen and dehydrated. Then when perfectly dry they are ground in a ball mill for two weeks. The ground organisms are then dissolved in phenolized saline and the nitrogen content determined. Stock solutions are made containing 10 mg./100 c.c. These are diluted for skin testing to 1:100. .1 c.c. used intradermally, containing .0001 mg. nitrogen. The follow-

 1—2 cms = ++
 2— or greater = +++

Tabulation of the tests revealed a number of interesting facts. In a grouping of the children according to age rather than according to disease as noted in Table I, it is shown that there is an increasing susceptibility to a positive reaction after the first year of age up to 13 years of age, and then a slight decrease in the number of sensitive individuals. This observation agrees with the records of Collis⁸ (1932) which show that the age period from 12 to 14 was that of maximum sensitivity and that no increase in incidence of reaction was observed in higher age periods. It appears that infants under one year of age rarely show a positive skin reaction to streptococcus nucleoproteins whether they have a history of streptococcus infection or not.

In Table II the reactions have been grouped according to age and according to certain diseases. The reactions in rheumatic children at all ages show a high percentage of positive responses. The same may be said of patients with scarlet fever at all ages. In the group who had tonsillitis excluding those who also developed either rheumatism or scarlet fever, a much lower percentage of positive reactions was obtained except in the older children between 10 to 15 years. In the group of children with other diseases many of whom were candidates for tonsillectomy with no history of infection other than frequent head colds, there was the lowest percentage of positive reactions. After ten years of age many children show a positive skin test regardless of the type of infection, though the children with rheumatic infection are more susceptible to this nucleoprotein than any other group.

Skin testing with the nucleoprotein was undertaken in 200 rheumatic children. A definite clinical diagnosis of rheumatic infection was made in all of them. Relatively few rheumatic children were tested under five years of age but as indicated in Table III the percentage of positive reactions was high at all ages. Of the 200 different children tested 149 or 75 per cent showed a positive nucleoprotein test.

Tonsillitis is recognized as an initial infection in a large percentage of rheumatic children. It has even been considered by some authors as a rheumatic manifestation. It is at any rate looked upon as a streptococcus infection in many instances. Scarlet fever based on the accepted etiology of the disease is undoubtedly the result of a streptococcal infection. The result of the streptococcus nucleoprotein skin test was compared in the children with these three types of infection. Obviously all three clinical diseases existed in some of the individuals. In order to compare the skin response in the three classifications, the children listed in the tonsillitis group were not known to have had either rheumatism or scarlet fever. The children listed under the scarlet fever classification may have had tonsillitis but have not had any recognizable rheumatic manifestations.

As noted in Table IV, the children with rheumatic manifestations reacted positively in 75 per cent of the cases while those who had scarlet fever tested during the course of the disease, reacted positively in 71 per cent of the cases. Tonsillitis, on the other hand, which had existed a short time prior to the skin test or even years before elicited a positive response to the nucleoprotein in 51 per cent of the children. It appears that the clinical manifestations termed rheumatic disease and scarlet fever are more likely to show a positive response to the heat stable extract of the hemolytic streptococcus than other infections such as tonsillitis.

A more detailed analysis of the reactions in the 200 definite rheumatic children as well as in the 47 children listed as questionable rheumatics has been made in Table V. Among the 86 children with active rheumatic disease, 86 per cent gave a positive skin reaction, while among the 114 inactive active cases 66 per cent showed a positive reaction. Of the 47 questionable rheumatic children 57 per cent were positive to the nucleoprotein test. The active cases showed such rheumatic manifestations as chorea, arthritis, and pancarditis. A positive skin reaction to the intracutaneous injection of hemolytic streptococcus nucleoprotein was present in a majority of patients with definitely active rheumatic disease but became less positive as the acute attack subsided. Similar observations have been recorded by Coburn,⁹ Gibson,¹¹ on the other hand, reported in his series of tests

that the highest proportion of positive skin reactions to the extract of hemolytic streptococcus was found in cases of chorea; afebrile cases were less hypersensitive and febrile cases were least sensitive.

Perhaps of greater significance than the number of positive skin reactions among the rheumatic children is the degree of the reaction to the nucleoprotein. All the tests were noted according to the degree of the reaction and are recorded in Table VI. The marked reactions designated as +++ were noted mainly in the children with rheumatic infection. A few occurred among the children with scarlet fever and tonsillitis. But practically none were found among the 300 children with other diseases. The same applied to the somewhat weaker reaction designated ++. Among diseases other than rheumatic infection the positive reactions were likely to be slight, while among the rheumatic cases the positive reactions were generally more marked or severe.

When one compares the results of the skin tests in rheumatic disease with other diseases, the preponderance of the positive reactions in diseases associated with streptococcal infection is readily discernible. Table VII shows the high incidence of positive tests in rheumatic disease, scarlet fever and lessened incidence in tonsillitis, which may in many instances be a streptococcal infection. In such infections as the common cold and otitis media, positive reactions are less frequent, while in the pulmonary infections and in nephritis the majority of the tests are negative.

A group of 302 children of various ages was tested to determine the effect of tonsillectomy on the intracutaneous skin test. The percentage of positive reactions among these children was about the same as among any group of non-rheumatic children. Thirteen children were retested three months after the tonsillectomy was performed. Practically all of them showed the same reaction as before operation. Eleven of the same children were retested six months after the operation. All but four of these children still showed the same reaction. These four children showed + whereas six months ago they showed ++. Additional studies will be made on these children to determine the effect of tonsillectomy on skin susceptibility to the nucleoprotein of the hemolytic streptococcus.

DISCUSSION

Can any significance be attached to a positive skin test with the hemolytic streptococcus nucleoprotein? The question is immediately raised, "Will not the other nucleoproteins produce similar reactions?" In this study no control tests were made except in a few instances where a boiled preparation of the nucleoprotein was utilized. It was found that the degree

of the reaction was in no way changed by this procedure. Sufficient tests with other products had been made by competent observers. Coburn⁶ showed that 90 per cent of all individuals skin-tested with nucleoprotein of *B. typhosus* reacted positively. On the other hand these same individuals showed positive response to staphylococcus nucleoprotein in only 20 per cent, and to non-hemolytic streptococcus nucleoprotein in only 10 per cent of instances. Gibson¹¹ likewise had shown that reactions to viridans and gamma streptococcus extracts show no significant difference as between rheumatic and control series. In view of these and other similar observations, no control studies were made.

The hemolytic streptococcus nucleoprotein has been compared with old tuberculin and with Dick streptococcal toxin. A positive reaction to the injection of old tuberculin into the skin is now universally held to indicate that the patient is hypersensitive to tubercle bacilli or their products. This reaction is specific and is strictly related to tuberculosis. The streptococcal nucleoprotein skin tests likewise indicate that the patient is hypersensitive to some streptococci but it is not specific for rheumatic disease. The streptococcal skin test differs from the tuberculin test in that it may not remain positive as the tuberculin test does. The hemolytic streptococcus nucleoprotein is quite distinct from the Dick streptococcal toxin which can be destroyed by heat and is neutralizable by a specific antitoxin.

There seems to be considerable evidence to show that a positive skin test with the hemolytic streptococcus nucleoprotein has some significance in the rheumatic child. Its almost complete absence in infants under one year of age suggests that these infants have not yet become infected with a hemolytic streptococcus or have not yet become allergic to its products. With increasing age there is more liability to infection with the hemolytic streptococcus as is shown by a greater incidence of rheumatic infection, scarlet fever, and tonsillitis. Parallel with this increase of clinical infections due to the hemolytic streptococcus is an increase in the number of children who react positively to this nucleoprotein. The positive reactions however are decidedly more likely to occur in rheumatic infection and in scarlet fever than in other diseases. Inasmuch as 75 per cent of these

CHART I.—Per cent positive reaction to hemolytic streptococcus nucleoprotein in various diseases.

children show a positive reaction and only about one-half as many at the same ages who did not manifest clinical evidence of these diseases it would seem to indicate that these children with known streptococcal infections become allergic to the organism or its products. Undoubtedly many children who react positively to this nucleoprotein may have been infected with the hemolytic streptococcus but no history of clinical manifestations was noted. It seems therefore reasonable to assume that a positive reaction to this nucleoprotein indicates the child has been at some time infected with the hemolytic streptococcus.

It is interesting to note that in addition to a higher incidence of positive reactions in children with rheumatic disease the degree of reaction was also more marked in those children. The +++ reactions are almost entirely limited to rheumatic fever patients and to those with known streptococcal infections such as scarlet fever and in cases of tonsillitis showing a high percentage of hemolytic streptococcus in the throat. One rheumatic patient tested with .1 c.c. containing .0002 mg. nitrogen showed a positive reaction measuring 5-6 cms. in diameter, and causing involvement of the lymphatics up the arm. It subsided with vesicle formation. In erythema nodosum the results are striking. Collis¹² has shown that mild or negative reactions are produced with this nucleoprotein in cases which are due to tuberculous infection, while strong reactions occur if the infection is of rheumatic origin. Similar results were obtained in our studies. Any patient with erythema nodosum should be tested with old tuberculin and with the hemolytic streptococcus nucleoprotein. This test undoubtedly has considerable clinical significance in searching for the etiology of this disease.

Observations on scarlet fever patients showed a high percentage of positive skin tests during the disease. At first the skin tests were made on them at various times during their hospital stay of 30 days until it was realized that some were negative at first and later became positive. Four cases were skin-tested at repeated intervals during their illness and a progressively increasing reaction was found, beginning to be positive in the first or second week and reaching the maximum in the fourth week. This is in agreement with McGibbon's¹⁰

results reported recently, who found that 90 per cent of scarlet fever patients gave a positive reaction to hemolytic streptococcus nucleoprotein in the fourth week of the disease.

No clinical significance can be attached to positive skin tests in non-rheumatic children as noted in this study. Among the 300 children who were tested prior to their operation for removal of the tonsils it was found that the highest percentage of positive tests was found among those children who gave a history of attacks of tonsillitis. Retesting a small number of these children three and six months after tonsillectomy, a weaker reaction to the nucleoprotein in a number of them was found, while the majority of the tests remained the same. It is suggestive that tonsillectomy may have relieved the focus of infection in these children as noted by the declining skin response to the nucleoprotein. Additional tests and observations will be made on these children to determine if any relation exists between the result of the test and clinical infection. No deductions can be made from this study other than to note that the results are in accord with previous reports made by other observers. It at least supports the contention that rheumatic disease may be associated with a streptococcus infection.

SUMMARY

Intradermal skin tests were performed in 835 different children with a hemolytic streptococcus nucleoprotein.

Positive skin reactions to this nucleoprotein are seldom present in infants and are most common in children between 10 and 13 years of age.

Rheumatic children, 200 in all, gave positive reaction in 75 per cent, and non-rheumatic children in 32 per cent.

Other streptococcal infections such as scarlet fever and tonsillitis gave a higher percentage of positive reactions than other infections.

Practically all of the +++ reactions occurred in the rheumatic children.

DISCUSSION

S W CLAUSEN, Rochester, N Y—The analysis presented by Dr Kaiser and Dr Keith of the reaction of the skin of children to the intradermal injection of the nucleoprotein of a hemolytic streptococcus is of importance in two respects

(1) The results support the hypothesis that infection with streptococcus is present in rheumatic fever. Complete proof of the streptococcal etiology of rheumatic fever is still lacking. It is known that rheumatic fever rarely occurs in the South, where tonsillitis and puerperal sepsis due to streptococcus are also rare, it is also known that recurrence of rheumatic fever often takes place two or three weeks after an acute infection with streptococcus. Recently, however, Duckett Jones has stated that streptococci cannot be found in the throats of a certain number of rheumatic patients, also that the febrile disorder caused by intravenous injection of typhoid vaccine in a person with quiescent rheumatic fever may be

followed by the development of very marked symptoms of rheumatic fever. Dr Kaiser and Dr Keith imply that the nucleoprotein used in their work might be more specific than the nucleoprotein from other streptococci. It would of course be of great importance to discover whether rheumatic persons are especially sensitive to a particular streptococcus, or whether they are sensitive to a large group of streptococci. It may be found that the skin reaction to the various nucleoproteins does not differ as much as certain other biologic reactions e.g., reactions between serum and the specific carbohydrates of the various streptococci.

(2) This paper also shows that the response of the rheumatic person differs from that of non-rheumatic persons even when they are infected with streptococcus. A very much higher proportion of young rheumatic children have developed sensitivity of the skin to streptococcus nucleoprotein than have children of the same age with tonsillitis. Scarlet fever also confers this sensitivity upon the skin of the majority of young children, but the sensitivity of the skin appears to persist much longer in the rheumatic children than in any of the other children. It would be of interest to know whether this means that a subacute or chronic streptococcus infection persists in such children. If this is the case, the test might be of value as a guide in the treatment of supposed foci of infection. If, on the other hand the positive skin test means the persistence of allergy without the presence of infection it might be of value as a guide in desensitization or as an indication for the continued use of salicylates.

GLAND TREATMENT FOR CHILDLESSNESS

The cause of childlessness in a large number of marriages as well as the cause of progressive deafness in fully two thirds of cases examined has been traced directly to improper functioning of some of the glands of internal secretion the closing scientific sessions of the clinical congress of the American College of Surgeons was told by a specialist in the endocrine field, as reported in the *New York Times*.

This role of the glands, which have been found to play an important part in other vital functions, was reported by Dr Allan Winter Rowe, director of research at the Evans Memorial Hospital of Boston.

Of a hundred childless couples examined, Dr Rowe stated fully half were restored to normal by the daily administration of a few drops of hormone extract.

Most of the infertility was laid to malfunctioning of the thyroid gland in the throat, the pituitary gland at the base of the brain, and the ovarian gland. By supplying the particular deficiency the condition was removed, Dr Rowe reported.

Incidence of the condition was evenly divided between men and women, Dr Rowe added. Among the 100 couples examined sixty nine persons were childless because of a deficient pituitary, and of these half were men. In each of these cases the administration of pituitary extract brought the patient back to normal.

Twenty seven cases were traced to thyroid trouble and of these twenty one were men and only six women. In all, fifty six men and sixty-one women have been restored to normal by correcting the glandular abnormality.

In cases of progressive deafness known as otosclerosis Dr Rowe stated that fully two thirds of the cases examined by him could be traced to the malfunctioning of either the thyroid, pituitary or some other gland. In all of those cases the hearing was definitely improved by an artificial supply of the deficiency.

The examination of a large number of school children Dr Rowe reported also revealed that mental backwardness could be traced to glandular under functioning.

Louis J Auerbacher, the first to suggest that the Vitamin D irradiation of milk might be an effective means of curbing infantile rickets and the man who launched the successful experiments toward that end in association with the late Dr Alfred F Hess has been appointed Director of Medical Relations of the Borden Company.

Mr Auerbacher is vice president of the Dry Milk Company Inc, one of the affiliated organizations of the Borden Company. His new duties include contacting the medical profession regarding all phases of research on milk and milk products.

ARTERIOGRAPHY

JOHN C. KNAPP, M.D.

*From the Department of Radiology, St. John's Hospital, Brooklyn
Woodhaven, Long Island*

Reynaldo Dos Santos and his associates in their excellent work, *Arteriographie des Membres et de L'Aorte Abdominale*, published in 1931, gave the history of arteriography. It is stated that as early as 1896 observers in France, Italy, and Germany radiographed the peripheral circulation in the cadaver by the injection of radiopaque substances such as bismuth. As early as 1910 attempts were made to visualize the arteries in the living subject but the first practical work was really begun in 1924 by Sicard and Forestier using Lipiodol and by Berberich and Hirsch with a solution of strontium bromide and by the American Brooks using a solution of sodium iodide. Dos Santos and his co-workers began their work in 1929 using various radiopaque solutions. In this country in 1932 and 1933 E. V. Allen and J. D. Camp of the Mayo Clinic have done some excellent work along this line.

The arteries of the periphery can at times be visualized when sclerotic or when sufficiently calcified to cast a reasonably dense shadow. This type of visualization gives us very little information as to the size of the lumen, the flow of the bloodstream, and the extent of occlusion of the vessel lumen. This method does not visualize aneurysms or aneurysmal dilations.

In such diseases as diabetes with arteriosclerosis, endarteritis, and allied conditions it is often of greatest value to determine the exact condition of the vessels involved. The intra-arterial injection of some radiopaque solution is necessary for a direct study of the peripheral vascular system. The ideal solution for this purpose should be non-toxic, non-irritating, and readily excreted. Such a solution has as yet not been found. Various solutions of iodides, bromides, as well as solutions containing organic iodine such as skiodan, iopex, and the like, have been used. In the proper concentration for good visualization these solutions have been found painful and irritating to the lining of the arteries and not entirely free from toxic effects.

We have found the most satisfactory solution for this work, while not ideal, to

be best for our purpose at the present time. This is a solution of 25 per cent thorium dioxide and manufactured under the trade name of "Thorotrast." The solution is non-irritating and used in the amount ordinarily necessary for good arteriography, has been found to be non-toxic. The disadvantage of the solution lies in the fact that the thorium salt is picked up by the reticuloendothelial system and deposited in the liver and spleen. It is excreted extremely slowly but various investigators agree that it is apparently harmless in small amounts.

Arteriograms have been made of nearly all the main arteries in the living subject, such as the carotid, pulmonary, and the abdominal aorta. The procedures for injecting these large vessels necessitate a special technic and are not at present of much definite diagnostic value. The arteriography of the vessels of the extremities, however, is much simpler and has a very definite diagnostic value. The arterial state of the femoral is most frequently desired and the brachial in a few selected cases.

TECHNIC

The technic of arteriography at St. Johns Hospital is as follows: An ampoule of thorotrast of 12½ c.c. is diluted with normal saline to make a volume of 25 c.c. The artery selected is punctured under aseptic conditions with a number 18 gauge needle attached to a syringe containing the diluted thorotrast. In the case of the femoral this injection is made in the upper part of Scarpa's triangle. In the case of the upper extremity any point in the brachial, above the elbow, may be selected as the site of the injection. The solution is injected at the rate of 3 c.c. per second, and the radiograph is taken as the last 5 c.c. are being injected. It is essential that the x-ray exposure occur during the course of the latter part of the injection. The lower extremity is best taken in the lateral plane. The exposure time is ⅓ second. The distance is 48 inches with low kV voltage and 10 m.a. current.

It is of considerable advantage to have the entire arterial tree in the lower extremity from the point of injection to and including the foot on one x-ray negative. This can be obtained by the use of a special cassette 3 feet long and 8 inches wide.

In the upper extremity where a tourniquet or an inflatable cuff can be applied proximal to the point of injection the extremity may be taken in two planes at one injection. This is not possible in the lower extremity because of the high point of injection.

Fig. 3—Complete occlusion of the femoral artery due to sclerosis in midthigh with re-establishment of the vessel by collateral circulation

Fig. 4—Complete occlusion of femoral at the popliteal bifurcation in cases of diabetic gangrene of the foot

INTERPRETATION OF ARTERIOGRAMS

The interpretation of arteriograms requires special study. There are many possible technical and other errors which cause misinterpretation of the x-ray negative. Improper injection of contrast medium, insufficient quantity to completely fill the vessels, and improper taking of the radiographic exposure are some of the possible

Fig. 1—Normal arteriogram of the lower extremity

Fig. 2—Popliteal aneurysm containing a large thrombus with gangrene of foot and leg.

sources of error. Spasm of the vessel wall may give an entirely wrong impression and if it is found to exist it may be eliminated by a low spinal anesthetic to block out the sympathetic influence. This spasm is liable to occur particularly in thrombo angiitis obliterans.

The interpretation of the arteriogram will depend on such factors as: (1) Congenital anomalies; (2) changes in the vessel lumen from a very slight constriction to complete occlusion; (3) extent of collateral circulation at the point of occlusion; (4) presence of dilations or aneurysms.

The normal artery presents a smooth homogeneous outline. In thrombo angiitis obliterans the vessels are irregularly reduced in caliber. The process usually begins in the small peripheral vessels and progresses in a proximal direction to the point of complete occlusion.

The arteriogram in arteriosclerosis on the other hand shows an irregularity in the vessel wall and in the lumen corresponding to the extent of the sclerosis present. This process is usually more noticeable in the larger vessels as in the femoral and popliteal.

The femoral may be occluded in mid-thigh with such extensive collateral circulation at the point of occlusion so as to nearly re-establish a normal lower femoral vessel or there may be a complete occlusion at the popliteal bifurcation at which point the collateral circulation is not sufficient to re-establish circulation. The presence of aneurysms is usually quite obvious. The presence of large thrombi in aneurysms may also be easily seen.

The value of arteriography to the surgeon in arteriosclerosis and thrombo angiitis obliterans with gangrene of the feet or toes is very great. It determines the site of occlusion, its cause, whether due to sclerosis or endarteritis and the extent of collateral circulation. These facts are a great aid in determining the point of amputation and the prognosis based on the extent of the collateral circulation.

ACKNOWLEDGMENT

I am deeply indebted to Dr. Carl H. Greene for his kind co-operation and assistance. The interest and help of Dr. Greene has made arteriography possible in this department.

"ANTISEPTIC" ADVERTISING

The patent-medicine brigade have seized upon the surgeon's use of antiseptics and are trying to make the public believe that they should have antiseptics everywhere in the house except on the dinner table, and even then in the pocket. Shrewd advertising, says a statement from the Consumers' Research Bureau, of Washington, New Jersey, has made an apparent daily necessity out of what is a rather rarely needed household article. Normal skin when clean and dry disinfects itself rapidly. The normal secretions of the lining membrane of the nose and mouth have a natural antiseptic or protective power, as do likewise the secretions of the mucous surfaces of the vagina. Most bodily tissues, indeed, do better with the least medication possible, and the recent current campaigns to persuade everyone to regiments of "antiseptic" inhalants, mouth-washes, gargles, douches, and so on, are absolutely against medical evidence, and are purely business-getting enterprises.

Such antiseptic rituals are costly to the consumer, often harmful to his bodily tissues, and exceedingly profitable to the patent-medicine industry—a generalization which applies to many so-called ethical and reputable products as well as to the common fakes and nostrums advertised in standard popular magazines and newspapers.

The unwise use of an antiseptic or the use of the wrong antiseptic for a given purpose may seriously retard recovery, by destruction of reparative tissue, may cost a life, or result in the

amputation of a limb. Advertising claims are not to be trusted in this field. Even brine and vinegar are stronger antiseptics and disinfectants than some proprietary products widely sold as potent germicides.

Dirt and oil increase the likelihood of infection. Hot soap suds made of laundry or toilet soap compare favorably, in the removal of germs on the skin, with most disinfectants and antiseptics on the market, being like them effective against a few organisms but not against most of the common ones. The cocoanut oil soaps, which are rather irritating to the skin, are regarded, among soaps, as the more efficacious skin disinfectants.

It is important in every case to note that antiseptic, disinfectant, and germicidal substances are not usable interchangeably. Each, silver protein or iodine, for example, has its own field wherein it is potent or safe. No antiseptic should ever be used without full understanding of its limitations and of its field of utility.

No proprietary mouth wash is, indeed, useful or effective in the ways usually claimed. The healthy mouth does not need a mouth wash—persistent use in the normal mouth may indeed be harmful; the unhealthy mouth will require more definite and specialized treatment than use of a proprietary mouth wash. Antiseptics capable of actually sterilizing the tissues of the mouth will destroy them, and if sterilization were possible it could last but a few minutes at best.

THE PHYSICIAN AND PHARMACIST OF THE FUTURE

FREDRICK D. LASCOTT, B.A., B.S. PH.G.

New York City

Meetings of physicians and pharmacists are not new by any means. As far back as 1224, Frederick II of Sicily in an edict, declared that "prices charged for medicines were to be regulated and the physicians were forbidden to share in the profits of prescriptions by clandestine arrangements with the confectionarii [pharmacists]"

In France during the sixteenth century, however, the relationship between physicians and pharmacists was not so harmonious. Disputes reached such a serious point that the physicians wrote prescriptions for only simple remedies which could be supplied by herbalists.

How History repeats itself!

For the last decade, the pharmacist has had to listen to the jibes of his brother, the physician as well as the general public concerning his ability or lack of ability as the case may be, "of properly preparing a salad dressing or making a club sandwich." He has listened good naturedly but nevertheless in many cases it has hurt his pride and justifiably so. He began to question the wisdom of his attendance at the College of Pharmacy or the years he spent as an apprentice doing everything from powdering corks to filling capsules of zinc valerate. Fresh from college, having heard speeches at commencement concerning the honorable profession of pharmacy and its importance in relation to medicine, he entered the drug business with the hope that the knowledge gained would be put to use. Aptly expressed by Robert Louis Stevenson, "It is a sore thing to have labored along and scaled the arduous hilltop and when all is done, find humanity indifferent to your achievement."

He studied the prescriptions which were brought into the store but instead of finding the tinctures, infusions, decoctions, troches, and so on, about which he had learned, he began to realize that the only thing for which he used his spatula was to remove labels from patent medicine bottles.

The time soon came when he noticed that the patients, realizing that the physician was prescribing proprietaries, began

to read off prescriptions. True sometimes when a physician wrote for Argyrol, the patient would get Agarol or *vice versa* but after all the pharmacist was not given that valuable document to study. And then the physician began to find that self-medication suddenly took an alarming increase. "Dr. Jones only prescribed some So and-So's Aspirin Tablets and some So and-So's Vapomear when I had a cold, why don't you try it?"—and the patient did, until finally pneumonia developed and Dr. Jones had to be called in anyhow. He was tickled pink when he called his pharmacist for pneumonia serum and he was able to supply it and happily give him the benefit of his knowledge of its administration. Old Doc Jones may even have felt a bit guilty for having teased friend pharmacist about his soda fountain.

But let us for a moment study the whys and wherefores concerning the soda fountain and luncheonette and hardware departments of the drug stores of the last decade. The pharmacist had to pay his rent, and other expenses and try to have something left over, and so, much against his wishes, he put in these sidelines. And since so much has been blamed on prohibition let's put a little more on the list. The soda fountain took the place of the bar for a quick lunch. Now with the repeal era well under way, except for a few States, and the return of the bar, a serious blow has been struck at the soda fountain. We see also the great increase of professional pharmacies. New ones are being opened daily. Pharmacies whose one thought is to serve the physician and the public.

A number of my students have come to me for my opinion in this regard and I have told them that I think the time has finally come when there is to be a separation between the professional pharmacy and the department store type drug store where the drug department is usually no larger than a telephone booth.

What must the pharmacist do to help warrant the confidence and support of the physician of the future and what must the

physician do to encourage the pharmacist of the future to once again be his right hand man in his battle against disease?

Both professions must clean house.

Chapter Two of the code of Ethics of the A.Ph.A. entitled, "The duties of the Pharmacist in relation to the Physician," states as follows:

The pharmacist even when urgently requested to do so should always refuse to prescribe or attempt diagnosis. He should under such circumstances refer applicants for medical aid to a reputable legally qualified physician.

I know that most pharmacists are strict in following the above mentioned dogma, but the small percentage who do violate it, are the cause for criticism of our entire profession.

Since the Supreme Court handed down the decision that the Ownership Law was unconstitutional, there has been a tremendous increase in the number of non-pharmacist owned drug stores and the subletting of prescription departments by cut-rate cosmetic shops to men who in most cases could not find employment in reputable pharmacies.

These individuals are responsible for much of the criticism wrongfully heaped on the shoulders of the conscientious pharmacist who has striven to abide by the ethics of his profession. It is this type of store which is largely responsible for the counter-prescribing and so-called diagnosis which the honest pharmacist does not tolerate and which the physician is justified in criticising.

A friend of mine had an experience a few weeks ago, which in addition to a lesson in ethics taught one of his clerks a lesson in economics. A maid employed by one of his customers rushed into the store with a handkerchief covering the palm of her hand. She had cut herself while opening a bottle and tearfully asked to have the wound treated. The pharmacist immediately informed her of the danger of infection and suggested she see her physician. Inasmuch as he lived some distance away, she asked the pharmacist to suggest someone in the neighborhood. He called a young physician who had just located close by and asked him whether he would be kind enough to see a patient immediately.

As she left the store for the physician's office, his clerk, recently employed in a cut-rate cosmetic shop, turned to him and said that he could have turned that into a sale of at least \$1.50 what with bandages, per-

oxide and adhesive and cotton, and very subtly inferred that the proprietor's salesmanship was lacking.

The proprietor dismissed the matter but felt very much pleased a short time later when the maid returned with her hand neatly bandaged and two prescriptions to be filled—one for a solution of bichloride and the other for Elixir Triple Bromide, N.F. She thanked him profusely for having referred her to the doctor who had removed two slivers of glass from her hand and had told her of the pharmacist's wisdom in suggesting immediate and proper medical treatment. In a few minutes the physician phoned to thank him for referring the case to him and they since then have had very cordial relations.

You can picture the delight with which the pharmacist had his clerk ring up the sale which he assures me was considerably more than the amount the clerk had mentioned.

What had the pharmacist accomplished:

1. He had done the right thing for the patient (preventing infection, and so on).
2. He had made a friend of the physician.
3. He had incidentally made a sale without feeling that it was not completely legitimate.

Now what about the physician and his part in pharmacy of the future. He too should take steps to bring about this Utopian harmony of the two professions.

Fortunately, self dispensers are on the decline because the public is sufficiently intelligent to realize that a physician except for emergency cases cannot possibly stock the variety of medicines required for every type of illness. The physician who prescribes proprietaries is encouraging the use of patent medicines indiscriminately.

I have to think of the story of the wise old man who went to his physician for a physical examination. After the examination, the doctor, although finding nothing wrong, told him to get some medicine at the drug store. He asked the doctor how much he owed him and the physician said \$5.00. "Here it is. After all, the doctor must live," was his parting remark. He went to the pharmacist, obtained the medicine and upon asking how much it was, he was told \$1.00. "Here's your dollar. The druggist must live," and thereupon he went home, opened the bottle and poured it carefully down the sink and said, "Alas, I too must live."

True, we all must live, but we must not force the public to spend their money on medication whose success in many cases is only due to high pressure advertising.

A large number of manufacturers, to introduce a pharmaceutical product, start by soliciting the physician and when it has been generally accepted, advertise it directly to the layman. The prescription proprietary of yesterday is the patent medicine of today. The prescription proprietary of today is the patent medicine of tomorrow.

Why must there be twenty-eight brands of digitalis when they are now all standardized? Why must there be sixty-three brands of ephedrine when any good pharmacist is able to prepare oily and aqueous solutions of the salt? The same applies to the many high-priced proprietary sedatives that have in recent years duplicated such splendid formulas as Elixir Three Bromides and Elixir of Paraldehyde.

U.S.P. and N.F. preparations are of proven and tested worth. Both books are revised every ten years by a committee of non-paid physicians and pharmacists of unquestionable integrity and exceptional experience in their respective fields.

Many—of course, not all—prescription proprietaries are nothing more than attempts to duplicate other proprietaries or in some cases official preparations cloaked by trade names and subsequently higher priced. The patient must pay for the tremendous expenses involved in advertising and detailing the physician.

Let us forget the past.

Gentlemen of the medical profession of the future!

Watch out against the growing tendency toward socialized medicine. You must, wherever possible, eliminate economic waste.

Remember that every time you prescribe a prescription proprietary—using a brand name—you cause some pharmacist to increase his stock—increase his overhead—and naturally increase the cost to your patient. The only excuse for prescribing proprietaries should be when the official books do not have a preparation of equal therapeutic value—and in case you are not aware of the many splendid formulas in the U.S.P. and N.F. your friend, the pharmacist will gladly assist you by presenting you with a condensed formulary supplied by the New York State Pharmaceutical Association.

And now members of the Pharmaceutical Profession of the Future!—

Show your colleague, the physician, that you will continue to merit his confidence. Stick to pharmacy, that grand old profession, but don't rest on your laurels. Keep your stock of U.S.P. and N.F. preparations fresh, continue to assist your friend the physician by having biologicals properly stored and a complete stock for his immediate needs.

Improve your equipment. Throw away the "No Admittance" sign from above your Prescription Room Door. As a matter of fact throw away the door. Let the physician see what goes on in your "Sanctum Sanctorum."

Supply him with formulas which will encourage him to prescribe real prescriptions and not force him to rely on patent medicine vendors. Advise people to visit their physicians periodically and so show him that you are working with him and not against him in what, after all, is the basis of both of these noble professions.

"The untiring battle against disease and the improvement of the health of our fellow beings."

1209 LEXINGTON AVE.

HOW NOT TO GET THIN

That seems to be the advice needed by thousands who are going at it in unwise and even perilous ways. The Chief of the Division of Public Health Education of Pennsylvania declares that it is only "a very true though sad fact" that hundreds of women have killed themselves during the past decade by senseless and excessive dietary reduction practices. Caught in the wave of mass psychology which emphasized the so-called athletic figure, legions of misguided members of the feminine contingent were attracted to hazardous drugging and misguided

food practices. Premature funerals, not to mention countless prolonged illnesses, just naturally followed. All of which, he adds, goes to prove that the way to get thin is first not to get fat; and second, if over weight, then to see one's physician and be guided by his directions.

Millionaire Octogenarian: "Will you marry me if I have my health rejuvenated?" Pretty Gold Digger: "I'll marry you all right, but you leave your health the way it is."—*Oral Hygiene*.

Recent Events

It is unusual during the course of administration affairs to pause long enough to summarize accomplishments. But two recent events are noticeable in that they mark progress. In the first place, the discussion at the recent Council meeting, and at the Conference of Committeemen and officers, cleared away uncertainty and clarified mooted questions and demarcated immediately objections. In the second place, the new Committees which are under way started activities. The Committee on Trends is under way. The Committee of District Branches is organized. From the one, "The Romance of Medicine," will reach the public to whose service, all our efforts are dedicated, and from the other there should result regional conferences which having a common objective, may well result in working out schemes and plans, suitable for given localities.

We have two major problems crying for solution. First, the medical care of the indigent. These are wards of the community in which they reside, and the responsibility for them is community business. The doctor should not be doubly

taxed. On the one hand, he carries his share of the burden as a taxpayer, and, on the other hand, again as a physician he is taxed by giving his services gratis. Medical care of the indigent should be paid by the community alone.

The second major problem is to find ways and means of overcoming the economic barrier which among wage-earners in the lower income groups prevents modern medicine from delivering them its best. President Roosevelt has said that "the care of the sick is a local responsibility." The set-up by the District Branches makes it feasible to achieve accords in each locality on these problems.

Finally, there is our concern with legislation. We shall endeavor to maintain unimpaired and intact the Medical Practice Law; we shall endeavor to keep unhindered and unhampered by restrictive legislation those in our ranks who day in and day long are searching for medical truths through animal experimentation and other research; we shall try to curtail the activities of "cults" and "cultists," and strengthen preventive medicine where health laws need strengthening by adoption of new measures to protect the public health, and lastly, we shall help with all honorable means at our command to rectify the abuses and racketeering which has developed in the operation of the Workmen's Compensation Laws.

Let's Correlate the Groping Units

"Must we go on in many groping, disorganized, separate units to defeat, or shall we move as one great team to victory?"—FRANKLIN D. ROOSEVELT.

In our ranks are many organized groups having objectives which are not always those of organized medicine. Occasionally, that for which they strive is in direct opposition to the stand taken by our State Society. In the results of the crusading spirit of those sincerely endeavoring to accomplish their purposes, the great public, and sometimes the legislature, sees the profession divided into many groping separate units. This division of the profession into separate units has become

marked especially since the publication of the Report of the Committee on Medical Care, and the discussion of the panacea which it recommended to all. In line with the action of the Medical Society of the County of Monroe, we too are "lacking in confidence in the panacea effect of solution of the problem by insurance action except under rate sociological groupings which we do not believe are existent in our Country."

Our society has repeatedly recorded its position in opposition to compulsory health insurance. We cannot doubt the sincerity of the medical groups among us who differ from our viewpoint. A few of them only can be said to be swayed by their own personal economic stress under which the present day finds them.

The JOURNAL's news columns (on another page in this issue) contain the report of an action by the Council, wherein there is set up machinery by which it may be possible to establish one great team. Great is the responsibility of the District Branch Presidents, in that success or failure of the plan will depend upon the manner of men selected to carry out the onerous duty of finding and achieving a mutually acceptable thetic formula to which all medical practitioners can subscribe.

Too often, medical groups are the slaves of their specific differences. Their flatterers who live off them, intensify these differences to stimulate their vanity and provide medico-political occupation for themselves.

Ours, on the contrary, is not the rôle to accentuate differences but to find and promote the common purpose.

A Scholar in Surgery

He used to surprise us years ago when we were internes. "We will go to your rooms" (near the Operating Room) "and collect all the books you have on this subject and mull them over." There succeeded memorable moments of reading, discussion, classification of knowledge, and conclusion. He never hurried, never wasted time, never stopped until all the work was done, but he was always studying, capturing events,

reviewing and reclassifying information for us. He taught by making us feel that we were helping him to study. Later we learned that if you wished any special information on a surgical subject he could name the work, volume, and page where it was to be found, whatever its date or language. A few days ago he passed away in his ninetieth year. A host of reasons call his profession to attention and meditation. For the JOURNAL, let it suffice for the moment that he was twice president of his County Society and once president of the Medical Society of the State of New York.

Born in 1845, one of five children of a pioneer itinerant Methodist clergyman in the Middle West, he was trained in the self-help, co-operative spirit, resourcefulness, and economies of a parsonage where the average income was five hundred dollars per year and the highest less than a thousand. By happy arrangement the family resided in Ann Arbor, Michigan, for seven years, and the educational advantages of the schools and university were available. Religion and education were stressed in the home. Frugality and working for each other were necessary.

Upon graduation, came a postgraduate year in chemistry and premedical subjects leading to a master's degree. During the Civil War he enlisted as a hospital-steward in 1863, and was assigned in January, 1864, to a regiment of colored cavalry at eighteen years of age. Soon he was transferred to a general hospital in Springfield, Missouri, and mustered out in September of '65. At once he returned to the university from which he received his degree as Doctor of Medicine the following year, credits being given for his premedical scientific year and his service in the army.

When Harper Hospital of Detroit needed a house surgeon he won the position. His superiors there were men of large experience. "At the flame of their enthusiasm and ambition I lighted my own torch which has never since been extinguished."—Realizing then that his training was still quite incomplete he spent the winter of 1867 in a postgraduate course at Bellevue Medical School. Then came appointment as Assistant Surgeon in the

Navy in May, 1867. At Brooklyn Navy Yard, on the old U.S.S. *Pennobscot*, cruising the West Indies, and on the *Saratoga*, infested with yellow fever, he served.

After three years he married. In 1871, after the birth of the first son, ordered to indefinite sea duty, he concluded that he could not do justice to his family in the Navy and resigned. He regretted loss of associations he prized but placed family duty above all else. Slowly he established himself in general practice.

For ten years he taught Anatomy at Long Island College Hospital, serving as adjunct professor for three years. Then he was invited to become a member of the Managing Board to organize the proposed Methodist Episcopal Hospital. In 1884 he spent five months studying European hospitals and surgical clinics. Before his return the great founder of the hospital had failed, but one building of the several erected was completed in 1887, the staff was organized, and its work began. Until 1907 he served as Attending Surgeon when, differing in ideals from the management, he resigned.

Transforming his home into a private hospital he and his two medico sons developed their surgery in a new and intensive manner, winning applause from their professional colleagues. Ten short years full of joyous accomplishment were ended by the untimely death of the elder of the two sons, while the other was at the Mexican Border with the Army. The hospital was transferred to other hands. During those ten years notable contributions were made to the surgery of peri-colic membranes, of the prostate gland, of gastro-intestinal affections and their x-ray diagnoses, and of bladder tumors and surgical diseases of the kidney.

In 1878 he and a few ambitious friends had formed the "Anatomical and Surgical Society" and at the end of 1879 Volume I of the *Annals* of this Society was published. The second year came monthly publications by Putnam's Sons. This continued until 1884 and was the fore-runner of the *Annals of Surgery* which first appeared in January, 1885, the only journal in the English language devoted exclusively

to surgery. Until 1933 our "Scholar in Surgery" served brilliantly as its editor-in-chief. The benefits he thus afforded his profession and the world-public cannot be estimated.

During his long professional life he studied practically and recorded what he observed. During the decade 1872-82 his earnest researches were in the value of tracheotomy in laryngeal diphtheria and the fractures of the wrist. His contributions to literature on these subjects brought him his earliest large recognitions. How different from the work of 1907-17!

His writings in journals, monographs, books, chapters of textbooks comprise thousands of pages of careful, well-weighed, accurate writing in well-chosen words. His literary work was carefully planned and religiously followed. Once, for eighteen months, when contributing to a great System of Surgery, he arose at six and wrote from six-thirty to eight-thirty, appearing at his hospital at nine. Thus only could he make this contribution and leave his regular duties undisturbed.

Our "Scholar" trained surgeons of ability and distinction several of whom became devoted colleagues. Some are able writers. All realized his important influence. His standards were mountain-high and rock firm. Intellectually entirely honest, he sensed that "accuracy is the half-brother of honesty." As the scientific story was told, romance, color, drama were brushed aside to provide force for truth. This unswerving honesty held many close to him. Some accused him of severity and inflexibility. This apparent fault was due to an idealism which stood rigidly for truth and justice, scorning veneer. He had a warm heart but a serious demeanor. He possessed a keen sense of humor but no gift of frivolity.

A medical bibliophile, this Master found delight in accumulating rare volumes of historic merit. Priceless Vesaliana, works of Galen, Pare, Mundinus led the distinguished files. He delved into the characters of ancient anatomists and surgeons. He wrote of them in essays, deeming the most important that devoted to the Anatomist DaLuzzi (1265-1326).

His operative work was typical of the scholar. After patient, often long study of the case, a logical plan of treatment was evolved. His technical procedures were careful, deliberate, determined, and they fulfilled his plan regardless of scintillating suggestions by his assistants. During the case study he patiently considered every suggestion offered. The course once decided upon could be altered only by emergency or unexpected findings.

Patriotism strongly flavored this man's life and in his later years, when active surgical work had been relinquished, he was active in the Grand Army of the Republic. In 1921 he was made its Commander-in-Chief. He was a nature lover and delighted in his lakeside country home. He traveled widely and studied civilization and peoples.

A model of scientific industry, he was a student of extraordinary devotion. He had courage, a deliberate initiative, and exhaustless patience in all his work. He was sceptical about new discoveries and methods, willing to help prove their worth or unimportance, prompt in acceptance of proven facts. Discrimination was a principle. He advanced, sometimes slowly, but

always faced forward. He was sure of himself—but modest. After the profession of his city, state, and nation, had gathered to do him honor after fifty years of practice, he wrote the following comment: "Why then should this host of friends be assembled to honor one of their own number was a mystery to me. The greater number of them were themselves physicians, my neighbors, my rivals for popular esteem and service. To receive from such a jury such a verdict of approval after forty years of strenuous activity among them might well be a source of satisfaction. I appreciated it with all humility, as a movement upon the part of most of them rather to honor the ideals of professional life which I had striven to exemplify among them, than as a personal tribute to myself. In that spirit I could not fail to enter with joy and pride into the evening's mood." On that evening W. J. Mayo pronounced him to be "one of the greatest of surgical teachers-by-the-written-word."

Altogether the career of Lewis Stephen Pilcher was the conscientious conduct of a well ordered, scholarly life.

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked private. All communications must carry the writer's full name and address which will be omitted on publication if desired. Anonymous letters will be disregarded.]

December 27, 1934

To the Editor

At the last annual meeting in Utica I read a paper on "Gonorrhea in the Female" later published in the JOURNAL for August 15, 1934, p. 731, and find myself in consequence, in a peculiarly embarrassing situation. The paper was a compilation from well known texts and in no sense an original contribution. I announced at the meeting of the section that it was not original but largely taken from other sources. Unfortunately the manuscript reached your hands without quotations and references and when published gave the appearance of an original article.

This contretemps is entirely chargeable to my own inadvertence and thoughtlessness. I had not thought of publication and therefore failed to insert in the MS the quotation marks and

references that would have replaced my introductory remarks at the meeting. I greatly regret the erroneous impression of originality that my carelessness must have given and hope you will find a place in your columns for this application.

Also I wish to supply for the information of those who may have read the published article the definite sources and portions thereof which I included in my compilation paper. These are:

Graves Gynaecology, 4th Edition—Introductory paragraph page 197. Methods of abode page 197. Bacteriological requirements page 198. Conditions present for growth, page 198. Historical structure of cervix page 383. Genital tract which may be infected page 200.

News

of Interest to the Profession

THE COUNCIL:

ABSTRACT OF PROCEEDINGS AT THE MEETING OF DECEMBER 13, 1934

In addition to routine work the Council took definite action in the matters detailed below.

REPRESENTATION OF THE MEDICAL PROFESSION ON THE GOVERNOR'S SPECIAL ADVISORY COMMITTEE ON RELIEF AND WELFARE

The secretary was instructed to advise the Governor that the Council had designated Dr. Lawrence, the Executive Officer, to bring to the attention of the Governor the opinion of the council that there should be adequate representation of the medical profession of the State on his Special Advisory Committee on Relief and Welfare.

ELECTION OF CHAIRMAN OF THE COMMITTEE ON SCIENTIFIC WORK

For technical reasons there had been, for some months, a vacancy in this position. By unanimous vote the Council elected as Chairman, Dr. William A. Groat of Syracuse, who served in that capacity in the year 1933-34, with great success.

THE "TEN POINTS" AND COMPULSORY HEALTH INSURANCE

The Council formally adopted the following resolution, which was presented by Dr. Dougherty:

IN VIEW of the determined and persistent efforts of certain Foundations, Welfare Organizations, Governmental Organizations, and various groups of theorists with ideas based purely on sociological study, to regulate and govern the practice of medicine, the Council of the Medical Society of the State of New York deems it both wise and necessary to reaffirm the stand against Compulsory Health Insurance and the regimentation of the Medical Profession taken on previous occasions and to place the Society squarely behind Dr. Van Etten's "Ten Points" presented to and adopted by the 1934 House of Delegates of the American Medical Association in the following terms:

First: All features of medical service in any method of medical practice should be under the control of the medical profession. No other body or individual is legally or educationally equipped to exercise such control.

Second: No third party must be permitted to come between the patient and his physician in any medical relation. All responsibility for the character of medical service must be borne by the profession.

Third: Patients must have absolute freedom to choose a duly qualified doctor of medicine who will serve them from among all those qualified to practice and who are willing to give service.

Fourth: The method of giving the service must retain a permanent, confidential relation between the patient and a "family physician." This relation must be the fundamental and dominating feature of any system.

Fifth: All medical phases of all institutions involved in the medical service should be under professional control, it being understood that hospital service and medical service should be considered separately. These institutions are but expansions of the equipment of the physician. He is the only one whom the laws of all nations recognize as competent to use them in the delivery of services. The medical profession alone can determine the adequacy and character of such institutions. Their value depends on their operation according to medical standards.

Sixth: However the cost of medical service may be distributed, the immediate cost should be borne by the patient if able to pay at the time the service is rendered.

Seventh: Medical service must have no connection with any cash benefits.

Eighth: Any form of medical service should include within its scope all qualified physicians of the locality covered by its operation who wish to give service under the conditions established.

Ninth: Systems for the relief of low income classes should be limited strictly to those below the "comfort level" standard of incomes.

Tenth: There should be no restrictions on treatment or prescribing not formulated and enforced by the organized medical profession.

And, furthermore, (the resolution reads), to call upon the Officers, Committees, and all loyal members to oppose and combat these evils wherever and whenever occasion arises with the distinct purpose of making known to the public and to the profession at large the official opinion of organized medicine in matters of importance to both physician and patient.

NEW STUDY COMMITTEES SET UP WITHIN THE EIGHT DISTRICT BRANCHES

The following resolution, presented by Dr. Kopetzky, was formally adopted:

Resolved, That there be set up a committee in each District Branch to bring together organized groups which exist within the ranks of organized medicine, for the purpose of rendering available to the officers and mem-

bers of the Medical Society of the State of New York, the objectives, studies and purposes of these groups, and be it further

Resolved, That this committee endeavor by means of conferences and round table discussions, and any other legal means, to co-ordinate the endeavors of all members of the organized profession along parallel lines, within the framework set up by the Ten Point Program of the American Medical Association, and be it further

Resolved, That, where adjacent District Branches comprise a geographical unit, like the City of New York and its Metropolitan Area, the District Branches comprising such unit may be combined in the formation of this committee in carrying out the purposes of this resolution, and be it further

Resolved, That when and if common ground is found and a conclusion arrived at by any of these District Branch Committees, the Chairman of such Committee shall transmit his report to the Public Relations Committee, which may, at its discretion, hold further hearings and study upon the topics contained in such report, and after further consideration and deliberation make report to the Council, its Executive Committee, or directly to the House of Delegates, as the case may require, and be it further

Resolved, That the Public Relations Committee, receiving reports of District Branch Committees which are not in accord with one another, may at its discretion hold conference with such District Branch Committees which hold diverse views for the purpose of finding common ground between them, thereafter reporting its conclusions to the Council, its Executive Committee or the House of Delegates as the occasion may necessitate, and be it further

Resolved, That when and if the discussions at the Branch Committee make necessary co-ordination and the use of information possessed by the Committee on Economics, there then shall be representation from the Committee on Economics to the said Branch Committee. If conclusions are arrived at which would make co-ordination with the Committee on Economics necessary the good offices of that Committee shall be used, joint meetings held, and the results of such joint meetings and conferences reported to the House of Delegates, to the Council or its Executive Committee as the needs of the given situation may require, and be it further

Resolved, That no action at any of the conferences or committee meetings shall be deemed finally binding upon the State Society until approved by the House of Delegates, the Council, or its Executive Committee, and be it further

Resolved, That, pending discussion shall not be publicized to the general public, to the newspapers or to public officials. Publicity may properly be given in this relation to any conclusion arrived at which has received approval and endorsement by the House of Delegates, the Council or its Executive Committee.

AMENDMENT TO THE PUBLIC HEALTH LAW IN RELATION TO THE PUBLIC HEALTH COUNCIL HELD DESIRABLE

It was decided that it is very desirable to amend the Law in such fashion as to provide that when the Public Health Council promulgates amendments to the Sanitary Code such revisions shall not become effective until six months after they have been laid down.

It was also decided that the Law should be amended so that *two members* of the Public Health Council shall be practicing physicians.

COMMITTEE ON PUBLIC RELATIONS

The following recommendations of the Committee, designed to bring closer contact between welfare administrations, State and County Societies were adopted:

1. There shall be a local committee of the County Society, preferably a Public Relations Committee, to act as an advisory committee to the welfare administration in that county.
2. The State Committee on Public Relations shall through such local committee undertake to aid, assist, and instruct each County Society in working out the proper relationship between the physicians on the one hand and the law and local government on the other.
3. The Committee on Public Relations deems it necessary, in order to carry out the first and second recommendations, that the Executive Officer be instructed to act as its representative in conferring with the committee of each County Society, the county welfare officials, and other relief agencies, for the purpose of effecting a harmonious administration of medical law.
4. That the Executive Committee be invited to place this whole matter permanently in the hands of the Public Relations Committee, and that it direct the Executive Officer of the Society to act with the Public Relations Committee as may be necessary to maintain contact between the committee, and National, State, and County Welfare and relief agencies, and between the committee and members of the County Medical Societies.
5. Contingent upon the acceptance of the previous recommendations, we further recommend that the Executive Committee request each County Medical Society to appoint and authorize some permanent local committee, preferably its own Public Relations Committee, to deal with local welfare and relief officials who carry on the medical phases of local welfare and relief administration, and that this county committee be instructed to ask guidance and counsel from the State Public Relations Committee for such dealings.

COMMITTEE ON ECONOMICS

These recommendations of the Committee were adopted:

1. That the principle of periodic payment of the expense of medical care out of income, through established accredited agencies, be endorsed by the Medical Society of the State of New York,

2. That the JOURNAL Management Committee be authorized to publish articles dealing with this topic.
3. That the Committee on Economics be instructed to engage in conversations with representatives of the banking industry for the purpose of development of a concrete proposal

for the financing of the expense of medical care, provided, however, that there shall be no commitment of the Society to any agreement without consideration by and further instruction from the constitutional body.

D. S. DOUGHERTY, M.D.,
Secretary

COMMITTEE ON SCIENTIFIC WORK

ANNOUNCEMENT

The Chairman, Dr. William A. Groat, announces that applications for space in the Scientific Exhibit at the Albany Meeting, May 13, 14, 15, 1935, will now be received. Application blanks and other information may be secured from Dr. William A. Krieger, 103 Hooker Avenue, Poughkeepsie, who is in charge of the Exhibit.

The Scientific Exhibit is a feature of growing importance at the annual scientific assembly. There is no better method for presenting new research work promptly, or for illustrating clinical methods and results clearly and quickly to a large number of physicians.

It has been decided by the Executive Committee that awards of merit shall be made.

COMMITTEE ON LEGISLATION

BULLETIN NO. 1, JANUARY 8, 1935

The 1935 legislature has broken all records for promptness. The Senate reported 95 bills introduced the first day, while last year only 67 were introduced in the first week. And to prove that it was seriously in earnest that it shall do business from the first day, standing committees reported favorably on 13 bills on the second day. Hearings have been announced on important bills for the second week in January, another record. Among the 199 bills that are before both Houses, the following have a special interest for us:

Senate Int. 1, Byrne; Assembly Int. 1, Killgrew, Labor Law, creating an unemployment insurance fund and providing for method and mode of its administration and appropriating \$100,000. Referred to the Labor Committee.

This bill includes no medical phase and notice of it is sent you as a matter of information. We shall carefully read all bills submitted on this subject and call your attention especially to those that may contain a medical clause, since employment and good health are so closely related.

Senate Int. 18, D. T. O'Brien; Assembly Int. 18, Canney, amends the Workmen's Compensation Law, by requiring all workmen's compensation insurance, other than that carried by self-insurers, to be underwritten by the State Insurance Fund. Referred to the Insurance Committee.

This is one of the Governor's recommendations. It provides for the extension of the present State Fund. We have in the past opposed this measure but have felt all the while that it was growing in popularity. The objections we have had to it are based not on the principle involved but on the manner of administration. We have had many complaints from physicians claiming that the State Fund is more difficult to do business

with than any other insurance company; and we have also seen the present State Fund violate the spirit of the law, if not the letter, by designating physicians to whom employers carried by them should send their injured employees.

Senate Int. 19, N. A. O'Brien; Assembly Int. 19, Kantowski, amending the Workmen's Compensation Law and Labor Law, for eradication of medical abuses such as fee-splitting and solicitation of injured in connection with administering Compensation Law, by increasing from 10 to 15 number of members of Industrial Council, enlarging its powers and appropriating \$10,000. Referred to the Labor Committee.

This is a revision of the first printing of the Esquirol-Livingston workmen's compensation bill of last year. The revisions have improved the bill; it now provides that instead of a medical advisory council, the Commissioner of Labor and Industry shall have the advantage of five physicians added to his Industrial Council, making the Council hereafter a body of fifteen men, five representing labor, five representing industry, and five representing the State. This is a very desirable provision. We believe that if the Commissioner has the advice of five physicians on his Council many of the difficulties encountered in the past in administering and working under the Workmen's Compensation Law will be adjusted and eliminated.

Senate Int. 20, Coughlin; Assembly Int. 20, McCaffrey, amends the Workmen's Compensation Law by extending the law to embrace all disabling diseases and illnesses arising out of or in the course of employment. Referred to the Labor Committee.

This is the occupational disease bill that we have annually opposed. It is identical with the four or five bills that were before us last year. It would make all disabling

conditions incident to occupation, compensable. There can be no argument with regard to the principle involved, the difficulty again is a practical one incident to its administration. There is no definition of an occupational disease or disabling condition and it will encourage malingering among those who are inclined that way. The responsibility for justice will lie almost entirely with the physician, and we know how difficult it is to get a clear and concise statement of condition from our most cooperative patients. This bill also has been gaining popular support annually and now is one of the Governor's recommendations.

Senate Int 44, Ferron, appropriates \$3,000-000 for supplying undernourished and needy children babies and nursing mothers with fresh free milk, from moneys derived from bonds or borrowed in anticipation of receipt of proceeds thereof, authorized by Chapter 718, Laws of 1934. Referred to the Finance Committee.

Senate Int 45, Leason concurrent Assembly Int 45, Corbett. Assembly Int 70, Moffat. Senate Int 60, Desmond.

These bills are proposals for the reorganization of county government. We should be interested in all of these efforts to make certain that none is adopted which does not make satisfactory provision for public health and the practice of medicine.

Senate Int 67, Mandelbaum amends the Public Welfare Law, by reducing age limit for old age relief to 69 on July 1, 1935 to 68 in 1936 to 67 in 1937, to 66 in 1938 and to 65 in 1939. Referred to the Relief and Welfare Committee.

We should be interested in all moves made to reduce the age of eligibility for old age pension inasmuch as medical care for the pensioners is provided by the State.

Senate Int 77, McCall, amends the Civil Service Law by providing applicant for examination for position in competitive class must be a citizen of the United States and have been a resident of State for two years immediately preceding date of examination. Referred to the Civil Service Committee.

Let us review again our opinion of these bills. No 19 which is known as the "medical abuses" bill based on the report of the special commission appointed by the Governor a year ago and now carrying a provision for the addition of five physicians to the Industrial Council, giving Organized Medicine equal representation to that of Labor and Industry, is approved. We shall support this bill because we believe that the addition of physicians to the Industrial Council will obviate many of the difficulties of administration which in past years have annoyed and irritated the physicians.

Number 18, requiring all workmen's compensation insurance, other than that carried by self-insurers, to be underwritten by the State Insurance Fund. We have always opposed this idea, but the bill as drawn this year provides that it be administered by a special commission appointed by the Governor and that it be administered by the Commissioner of Labor and the Industrial Council. If bill number 19 is passed, physicians will be represented on this Industrial Council and we expect the administration of the fund to be more sympathetic to the practicing physician than the bills in former years offered. Therefore, our opposition to this bill will be tempered by the possibility of the enactment of number 19.

Number 20, the blanket occupational disease bill, has likewise been opposed by us in previous years although we have always maintained that the principle upon which it is based is correct, that if any disabling conditions incident to an occupation are compensable, then all should be compensable, but we have maintained that a blanket law will encourage malingering. When, however, the law will be administered by the commissioner advised by a council on which physicians sit, we can appreciate that malingering may be kept at a minimum much more so than would occur where the Advisory Council is composed of laymen entirely. Therefore, we are supporting this bill provided number 19 is enacted into law.

You will note that if this bill is enacted into law, applicants for civil service positions must offer citizenship in the United States and residency of two years in New York State immediately preceding date of examination.

Senate Int 98 Hanley, Assembly Int 53, Ehrlich amends the Labor Law, creating an unemployment reserve fund, employees to contribute 1 per cent of earnings, and providing for certain credit on State taxes for exempting certain employers or groups of employers for investment of fund in obligations of U S or any state, and appropriating \$100,000. Referred to the Labor Committee.

Another unemployment bill.

Assembly Int 59, Hamerman amends the Public Welfare Law by reducing from 70 to 65 years age of persons entitled to old age relief and permitting applicants not citizens but who have resided for 20 years in State to qualify for relief. Referred to the Judiciary Committee.

Another offer to reduce the eligible age for old age pensions.

Assembly Int 67, McGrath amends the Education Law, requiring public welfare officials to furnish indigent children with *car fares and eyeglasses*, and appropriating \$1,000,000. Referred to the Ways and Means Committee.

Assembly Int. 90, Whitney, amends the Agriculture and Markets Law to indemnify owner of bovine animal killed to prevent spread of Bangs disease for loss therefor, and appropriating \$1,000,000. Referred to the Agriculture Committee.

This year our bulletins are being sent to all of the members of the County Legislative Committees instead of to the chairman alone, as has been our custom. It is our idea that each member of every committee should be fully informed upon the legislative problems that the Society is endeavoring to meet. We hope that you will read carefully our communications and elicit as much support for our program as possible. We know the value of having the support of prominent influential lay persons and we expect this widespread distribution of the bulletins to bring us greater support of that character. May we ask that you take this matter seriously, and when addressing legislators or lay persons, do not speak carelessly. Every year we have had instances where some physicians have, in their enthusiasm, asked legislators to oppose bills that were never introduced; for instance, last year there were several occasions when men wrote to their legislators opposing the advancement of a chiropractic bill. We know this to be a fact because the legislators showed us the letters.

Do not hesitate to write to Dr. Lawrence in Albany any time at all for any information you may desire regarding matters of legislation, the status of bills or the attitude of legislators. We wish to make the Legislative Bureau as useful to the members of the Society as possible.

There are still several County Societies which have not sent us the names of the members of their Legislative Committee. If the members of your committee do not receive this bulletin, please send us their names at once, because we must know how many bulletins to prepare and we can not have a large extra supply on hand, so that we

can not promise to supply with early bulletins persons whose names we get later on.

SPECIAL BULLETIN, JANUARY 9, 1935

Herewith you will find the names of the members of the Committees on Insurance and Labor and Industry in both Houses. Bills 18, 19, and 20 rest with these committees, as you have been informed. If any of the members of these committees are your own legislators, be sure to write to them giving your opinion of the merits of the bills; and it won't be a bad idea for you to send a copy of your letter to other members of the committees:

SENATE COMMITTEE ON INSURANCE

D. T. O'Brien, Chairman, New York; Thomas F. Burchill, New York; John T. McCall, New York; S. J. Wojtkowiak, Erie; H. L. O'Brien, Kings; Lazarus Joseph, Bronx; Frank B. Hendel, Queens; James A. Garrity, Westchester; Nelson W. Cheney, Erie; Joseph R. Hanley, Genesee, Wyoming, Allegany and Livingston; P. W. Williamson, Westchester; Martin W. Deyo, Chenango, Broome and Cortland.

SENATE COMMITTEE ON LABOR AND INDUSTRY

H. L. O'Brien, Chairman, Kings; William T. Byrne, Albany; Joseph D. Nunan, Queens; Ogden J. Ross, Rensselaer; S. J. Wojtkowiak, Erie; Edward J. Coughlin, Kings; David E. Doyle, Erie; Henry I. Patric, Lewis, Herkimer, Hamilton and Fulton; Joseph R. Hanley, Genesee, Wyoming, etc.; C. Tracey Stagg, Schuylar, Tompkins, Chemung and Tioga.

ASSEMBLY COMMITTEE ON INSURANCE

Edward S. Moran, Chairman, Kings; John H. Cahill, Albany; George W. Stewart, Kings; George F. Torsney, Queens; William Kirnan, Kings; Chas. H. Breitbart, Kings; M. J. H. McLaughlin, Bronx; James A. Burke, Queens; James J. Dooling, New York; Nicholas A. Rossi, New York; Hamilton F. Potter, Suffolk; J. Edward Conway, Ulster; Russell Wright, Jefferson.

ASSEMBLY COMMITTEE ON LABOR AND INDUSTRIES

Anthony Canney, Chairman, Erie; M. F. Breen, Rensselaer; Eugene R. Duffy, New York; F. J. McCaffrey, New York; Harold J. Crawford, Queens; Michael N. Delagi, Bronx; Joseph Di Fede, Monroe; James V. Mangano, Kings; Ralph Schwartz, Kings; Wilson Messer, Steuben; Harry E. Goodrich, Allegany; Edward K. Corwin, Schuylar; Wm. E. Morris, Saratoga.

Committee on Legislation

County Societies

Chemung

Meeting of the Chemung County Medical Society held at the Elmira City Club, December 12, 1934 (98th Annual Meeting).

Following the dinner the meeting was called to order by Dr. Kinner, the President. The Secretary read the Minutes of the last meeting; they were approved and accepted. The Secretary then read the Treasurer's Report; this was approved and was filed with the Minutes.

Dr. Colegrove reported for the Legislative Committee, that 213 bills were introduced at the last session of the New York Senate. Only 32 of these bills were sent to the Governor of which he signed 14. These bills which were sent to him, all had the support of the New York Medical Society, except for the Osteopathic Bill, which fortunately the Governor vetoed.

Dr. Howland reported for the Public Health Committee, and stated that in the recent measles epidemic that there were about 2,000 cases reported to him and only 15 per cent of this total was reported by physicians.

He stated that his Committee had done no investigating into the Infant and Maternal Mortality as requested at the last meeting, by the Society.

Dr. Lewis reported for the Post Graduate Committee; he stated that he could not offer any definite course until he had had a conference with Drs. Farmer and Carpenter who plan to be in the city soon.

Dr. Lynch reported for the Economics Committee, and stated that steps had been taken toward the formation of the Physicians' Co-operative Association, and that this organization hoped to start the first of the year, and that the primary function of this organization was to educate the public.

Dr. Kinner requested that all members who had a copy of the Constitution and By-Laws of the Society submit them to the Secretary.

Election of officers was then in order. Dr. Stevens moved that the Secretary cast one ballot for the slate, nominated at the last meeting. This was seconded and carried. The officers for 1935 are: President, Dr. LaRue Colegrove; Vice-president, Dr. Charles S. Dale; Secretary, Dr. George R. Murphy; Treasurer, Dr. William J. Cusick.

Dr. Lynch then stated that the Society should take some action, as a result of the District Attorney's remarks at a trial, at which a person who we shall know as Mr. Roe made disparaging remarks about the medical profession. Following a discussion, Dr. John Burke moved that a committee of

three be appointed to draft resolutions to submit to the District Attorney; motion was seconded and carried. Dr. Kinner appointed a committee of Drs. Lynch, John Burke, and Butler. As there was no other business to come before the Society Dr. Kinner asked Dr. Lewis to introduce the speaker of the evening. Dr. Lewis then presented Dr. Kress, Director of the New York Institution for the Study of Malignant Diseases at Buffalo. Dr. Kress gave an extremely interesting and illustrated discussion on malignancy in general. He exhibited 176 slides by means of an apparatus, whereby he could show four slides at once. Following Dr. Kress' talk there was discussion and questions by Drs. Bleyer, Colegrove, Fish, Lynch, and Lewis.

Delaware

The Annual Meeting of the Delaware County Medical Society was held on December 18, 1934, and at this meeting the following officers were elected for the year 1935: President, Dr. Charles L. Wakeman, Andes; Vice-president, Dr. Orin Q. Flint, Delhi; Secretary-treasurer, Dr. William M. Thomson, Delhi; delegate to the Medical Society of the State of New York, Dr. Robert Brittain, Downs-ville; alternate delegate, Dr. Charles L. Wakeman, Andes.

The Committees appointed are: Censors, Drs. Dwight S. Hinsdale, Orin Q. Flint, and Edgar W. Hainlen; Public Health Committee, Drs. John H. Marsh, Clark S. Gould, and Charles L. Wakeman; Committee on Medical Education and Scientific Program, Drs. William M. Thomson, Thomas L. Craig, Dwight S. Hinsdale, and Walter E. Eells; Committee on Medical Economics and Public Relations, Drs. Donald R. Davidson, Floyd R. Bates, and James A. Holley. Committee on Legislation, Dr. William B. Morrow (of Walton) and Dr. Robert Brittain (of Downs-ville); Committee on JOURNAL Management, Dr. Thomas L. Craig, Davenport.

The Annual Meeting was small in attendance this year, because of a very bad night and very slippery roads. Dr. Harry Hall, of Oneonta, gave a well illustrated lecture on Sinus Infections.

Eric

Trudeau Memorial Luncheon. On December 12, 1934, Dr. Esmond R. Long of Philadelphia, Director of the laboratory of the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis, and Professor of Pathology at the University of Pennsylvania, delivered the principal address at a Trudeau Memorial Luncheon. His sub-

ject was Tuberculosis Through Fifty Years. The occasion commemorated the fiftieth anniversary of the first sanatorium for tuberculosis in America founded by Dr. Edward Livingston Trudeau.

County Society Working to Reduce Maternal Mortality. The work begun in April, 1934, has gone steadily forward. Instead of undertaking to make another careful and costly survey, the Society, considering that previous studies such as that of the United States Children's Bureau, "A Study of Maternal Deaths in 15 States," and that of the New York Academy of Medicine, "Maternal Mortality Survey in New York City," could be taken as applying in general, set out to put into effect in Erie County certain of the conclusions to which those studies led.

The program is thus stated in the Erie County *Bulletin* for November, 1934:

Certain objectives have been generally recognized as of paramount importance, by all students of the subject, as arising from the studies made. Among these are:

(A) Education of the Public.—Surveys have taught that chief dangers to mothers' lives involving the responsibility of the public come from: (1) Failure of the patient to co-operate with her physician during pregnancy. (2) Failure of patient to obtain prenatal care or realize its importance or to understand what constitutes a minimum standard of prenatal care. (3) Danger to mother's life from abortions (at least one-fourth of all maternal deaths are due to abortions). (4) Demanding painless childbirth at unwarranted risks. The New York City survey states: "The medical profession is obligated to inform the lay public that the operative delivery undertaken merely to alleviate pain or shorten labor involves increased risk for both mother and baby." (5) Refusal by the public to permit postmortems makes it impossible, in many cases, to determine the exact cause of death.

(B) Improvement of medical obstetrical practice through: (1) Carrying out recommendations of the United States Department of Labor, Children's Bureau for enlarged medical obstetrical teaching, including "larger and better facilities for clinical obstetrical training" which will give undergraduate students a wider contact with obstetrical patients. (2) Establishment by Erie County Medical Society (in co-operation with the Health Department, Medical School, University of Buffalo and Academy of Medicine) of post-graduate courses open to all physicians. (3) To institute whatever means may be necessary to raise general obstetrical medical standards so as to reduce to a minimum those maternal deaths which have been laid at the physician's door, in the various studies, as due to "errors in diagnosis, general incompetence, carelessness, tendency to underestimate seriousness of obstetrical operations." The committee will, as soon as possible, make available to all physicians in the county the recommendations and conclusions drawn by the most important surveys.

(C) Urge the adoption by hospitals of the table of "Standards" formulated by American College of Surgeons for "Hospitals Taking Obstetrical

Cases," plus the additional recommendations deemed necessary by the New York Academy of Medicine Survey Committee.

(D) Amending birth certificate to include information on type of delivery. The Health Commissioner of Buffalo and the Statistician of the Health Department are now preparing a supplement for use in connection with our birth certificate which will give information as to the type of delivery and other necessary data in connection with our study.

(E) Closer supervision of midwives and their annual registration.

(F) Working through proper agencies for improvements of obstetrical nursing.

(G) Arranging for the filling in of C.B. 122.—Revised U. S. Department of Labor Children's Bureau chart within one month of every maternal death, from hospital records and attendants and by interviewing attending physicians. These findings are to be immediately turned over to the Obstetric Study Group of the Maternal Mortality Committee.

The Board of Health has already made available to the committee photostatic copies of each death certificate in which the cause of death is connected with a pregnancy.

Joint Medical and Dental Meeting. On January 8, 1935, a joint meeting was staged by the Medical Society of the County of Erie, Buffalo Academy of Medicine, the Eighth District Branch of the Medical Society of the State of New York, the Buffalo Dental Society, and the Eighth District Dental Society. The essayist was W. R. MacAusland of Boston who spoke on the Importance of the Oral Cavity in General Health and the Far Reaching Consequences of Abnormal Mouth Conditions.

Franklin

The regular meeting of the Medical Society of the County of Franklin was held in the Nurses' Lecture Room of the Alice Hyde Memorial Hospital, Malone, on October 24, 1934. Luncheon was served in Hotel Flanagan.

Business Session: The Comitia Minora recommended the payment of the current bills. Secretary's and Treasurer's reports were read and approved. There were seventeen members present and six visitors. The Secretary was directed to cast one ballot for the following officers for the coming year. President, Dr. R. G. Perkins, Malone; Vice-president, Dr. Edward Packard, Saranac Lake; Secretary-Treasurer, Dr. G. F. Zimmerman, Malone; Censor for three years, Dr. Carter R. Morse, Tupper Lake; Delegate to New York State Society Meeting, Dr. C. C. Trembley, Saranac Lake; Alternate, Dr. J. E. White, Malone.

The following doctors were unanimously elected to membership in the County Society: Dr. William A. Gaspar, St. Regis Falls; Dr. Karl Fischel, Saranac Lake.

Dr. Schiff, Plattsburg, on the request of Dr. Thomas P. Farmer, Chairman of the

State Committee on Public Health and Medical Education, discussed the study of the high infant mortality rates in certain counties of the State, particularly the northern tier.

Motion was made by Dr. Perkins and seconded by Dr. Finney that the chair appoint a committee to study the infant mortality situation in Franklin County to ascertain the predominant causes of such mortality. The following committee was appointed by the chair: Dr. Daisy H. VanDyke, Malone; Dr. P. E. Stamatiades, Brushton.

Dr. R. G. Perkins discussed a communication in Social Insurance distributed by the Committee on Economics of the State Medical Society against the activities of certain lay agencies in the matter of Compulsory State Health Insurance.

It was moved by Dr. Finney, seconded and approved that the Franklin County Society Legislative Committee act upon this letter and use their judgment regarding the advisability of sending a telegram of protest to President Roosevelt.

Scientific Session activities enclosed.

Fulton

County Society Opposed to County Unit. At its annual meeting at Gloversville on December 20, 1934, the Fulton County Society adopted the following formal resolutions:

WHEREAS, The State Department of Health has established a Bi-County Health Unit comprising the counties of Montgomery and Fulton which has no definite plan and has been admitted by representatives of the State Department of Health to be a purely experimental procedure, and

WHEREAS, We believe such a movement in itself is an additional step toward State Medicine, and

WHEREAS, We believe such an experiment on the part of the State Department of Health is contrary to the principles of the American Medical Association. Therefore, be it

Resolved, That the Fulton County Medical Society regularly assembled in its annual meeting at Gloversville, on December 20, 1934, go on record as being unanimously opposed to the above program.

Genesee

The Annual Meeting of the Genesee County Medical Society was held on October 25, 1934, at East Pembroke. The following officers were elected: President, Charles D. Graney, Le Roy; Vice-President, Charles L. Davis, Batavia; Secretary-Treasurer, Peter J. Di Natale, Batavia; Delegate to State Society, Peter J. Di Natale.

Dr. Graney named the following committees: Public Health: Chairman, H. M. Spofford, Batavia; R. Frazier, Bergen; M. P. Messinger, Oakfield. Legislation: Chairman, P. J. Di Natale, C. D. Graney, R. G. Wilson. Physiotherapy: T. M. Steele, Le Roy. Medical Economics: Chairman, S. R. Hare,

Batavia; L. B. Manchester, Batavia; P. J. Di Natale, Batavia. Program: Chairman, P. J. Di Natale, S. R. Hare, C. L. Davis. Public Relations: Chairman, G. H. Knoll, Le Roy; C. D. Pierce, Batavia; C. C. Koester, Batavia. Membership: Chairman, W. B. Manchester, I. A. Cole, E. N. Morgan.

Rockland

Annual Meeting. On December 5, 1934, the Society held its annual meeting in time honored fashion as a "dinner meeting" at the Villa Lafayette, Spring Valley. These officers were re-elected: Dr. George M. Richards of Stony Point, as President; Dr. Alexander N. Selman, Vice-president; Dr. William J. Ryan, Secretary; Dr. Dean Miltimore, Treasurer; Dr. Royal Sengstacken of Suffern, Chairman of the Committee on Public Health; Dr. J. W. Eiles, Chairman of the Committee on Membership; Dr. Charles D. Hine, Chairman of the Committee on Legislation; Dr. Leo Weishar, Chairman of the Committee on Physical Therapy.

During the evening, A. Longfellow Fiske, radio speaker, gave an interesting talk on social problems. Knight McGregor sang several vocal selections. The meeting was, as usual, very well attended.

Seneca

The regular annual meeting of the Seneca County Medical Society was held October 11, 1934, at the Willard State Hospital. The meeting was called to order at 11:00 A.M. by the President, Dr. John F. Crosby of Seneca Falls. The following officers were elected for the ensuing year: President, Dr. E. M. Wellbery, Waterloo; Vice-president, Dr. Joseph E. Allen, Seneca Falls; Secretary-Treasurer, Dr. F. W. Lester, Seneca Falls; Censors, Drs. C. B. Bacon, Bel lows and Lester; Delegate to State Society, Dr. John F. Crosby; Alternate, Dr. L. Arthur Guild, Interlaken; Delegate to 7th District Branch, Dr. James M. Murphy, Waterloo; Medical Economics Committee, Drs. Edward M. Wellbery and F. W. Lester; Public Relations Committee, Drs. L. W. Bellows, E. M. Wellbery and J. E. Allen; Legislative Committee, Dr. F. W. Lester.

At 12:30 P.M., by invitation of Dr. Robert M. Elliott, Superintendent of the Willard State Hospital, the Society was entertained at dinner. At 2:00 P.M. the Society reconvened for the Scientific Session: Dr. Thomas P. Farmer, Syracuse, spoke on "The Treatment of Gynecological Conditions Met in General Practice." Dr. Farmer illustrated his talk with numerous lantern slides. In the discussion, led by Dr. Adrian C. Taylor of the Clifton Springs Sanitarium, many important comments were made. The paper of Dr. Farmer and the discussion following

it, which then became general, were well received by the Society.

"Classifications of Mental Disorders" was the subject of a paper by Dr. Ross E. Herold of the Staff at Willard State Hospital. This instructive paper was discussed by Dr. Herbert C. Burgess of Brigham Hall Hospital, Canandaigua.

After a rising vote of thanks to the host, to the speakers, and to the guests, for their excellent literary program, the Society adjourned.

Westchester

Fee Schedule of TERA Disapproved. At its annual meeting on November 20, 1934, the County Society adopted the following resolutions:

WHEREAS, The T.E.R.A. of New York State has issued a schedule of fees as the basis of reimbursement to the townships of the State for home relief; and

WHEREAS, This fee schedule has become in effect an arbitrary schedule of fees used by the town and county officials in Westchester County for the payment of all branches of the medical profession; and

WHEREAS, There is no evidence that the organized medical profession was consulted in the determining of these fees; and

WHEREAS, These fees, are for this county, in some instances absurd, and clearly inadequate to attract the willing services of the more competent physicians; and

WHEREAS, A subsequent development of welfare work has added State Employee compensation cases to the ordinary relief cases at similar fees, in subversion of the original intent of the act and with dangerous effect on the entire scheme of private compensation payment; therefore, by the Medical Society of the County of Westchester at its annual meeting in White Plains, on November 20, 1934, be it

Resolved, That the County Society disapproves the fee schedule of the Temporary Emergency Relief Administration and refuses to accept it as a permanent basis of payment to the medical profession of Westchester County and that in its opinion the members of the medical profession should continue to operate under it only under protest and only until a satisfactory fee schedule shall be adopted by the County and Town welfare officials; and be it further

Resolved, That the present arrangements whereby medical fees for services rendered injured employees of work relief agencies are paid out of welfare funds and the present schedule of fees paid for these services, shall be and hereby are strenuously protested as unsound and unfair arrangements; and be it further

Resolved, That copies of these resolutions be sent to the officers of the T.E.R.A., the County Supervisors, the Commissioner of Public Welfare of the County, the various local Welfare Officers of the County, and that they be furnished to the local press and that they be published in the *Westchester Medical Bulletin* for transmission to the State Society and to other County Societies and interested persons.

IT'S ALL IN THE DAY'S WORK

Georgia doctors are discussing an amazing operation performed by one of their number a few weeks ago in saving the life of a young man at the F.E.R.A. transient bureau in Atlanta. Dr. L. Minor Blackford really saved the young man's life twice, once at the risk of his own. The doctor refused to say anything about it, but his friends told the story and it is printed in the *Journal of the Medical Association of Georgia*, quoted from the *Atlanta Constitution*. It seems that the physician was called to the bureau to attend Herbert Conner, 28, ill with abscessed tonsils. He went without equipment and found Conner near death from lack of breath, the swollen tonsils closing the air from his lungs.

Working alone in a dimly lighted attic, Dr. Blackford used only his pocket knife to slit a hole on the youth's throat in order that air might enter the lungs. He then held the incision open with his hands and had an untrained man administer heart and respiration stimulants. Soon the air began to enter the lungs but as Conner was bleeding freely from the incision the blood also was entering the lungs as well as the air.

Then Dr. Blackford and his helper got an ordinary rubber tube which he sent down Conner's windpipe to the lungs and through this pipe the doctor himself sucked the blood from the patient's lungs.

After a long time the youth began to breathe

comfortably and the surgeon dressed his wound and put him to sleep.

The patient was reported to be doing well Thursday, as Dr. Blackford was receiving the plaudits of his profession, and he smoked a cigaret, blowing the smoke through the tube in his throat.

"I might have sucked the blood from the lung of someone near to me but it is only one man in a million who would have done what Dr. Blackford did and risk the chance of dangerous infection and possible death to himself," a prominent physician and surgeon said in discussing the exploit.

He had just hung up his shingle. That morning a stranger entered. The doctor asked to be excused as he hurried to the phone.

Taking down the receiver he said: "Yes, this is Dr. Whoosit. Yes, I will be ready for you at two-ten this afternoon. But please be prompt for I am very busy. Two hundred dollars? Yes, that was the estimate I gave you."

Hanging up the receiver he turned to the stranger, and rubbing his hands, asked: "Now, sir, what can I do for you?"

"Nothing," replied the stranger, quietly. "I only came in to connect the telephone."—*Thomas Topics.*

Physicians—Liability for Acts of Substitute Physicians

It happens at times in obstetrical cases that the physician who has been engaged in the case by reason of some unforeseen event is unable personally to be present at the actual delivery. Under the circumstances the doctor will, of course, provide another competent physician to deliver the patient.

An interesting case passing upon the responsibility of the first physician for the acts of the substitute physician is found in a case in one of the Southern States.*

In the case under consideration the facts were as follows: A certain Dr. M had agreed to deliver the plaintiff and had examined her at regular intervals. Shortly before the time when the woman was expected to deliver, Dr. M had a case in which he was defended coming up on the calendar. On the morning in question he saw and examined the plaintiff about 6:00 A.M. The reported case does not state what the woman's condition was at that time. By reason of the fact that Dr. M's actual appearance was required in court some distance from the home of the patient, he concluded that he would not be able to revisit the patient on the same day. The testimony in the case showed that it had long been the custom among reputable physicians in that locality where Dr. M practiced for a physician who was unable to meet all his professional engagements to send in this emergency another competent physician.

In accordance with that custom Dr. M communicated with one Dr. H, a competent physician in the field of obstetrics, and explained the situation, and Dr. H agreed to take the case over. In a telephone conversation with the husband of the patient Dr. M explained the situation to him and the husband agreed to accept the services of Dr. H. In the course of the conversation between the two physicians mention was made of Dr. M referring to the case as a partnership case. The mean-

ing of this is not very clear for the reason that there was no existing partnership between Dr. M and Dr. H. One was not in the employ of the other, but we mention this fact because it is later commented on by the court.

In pursuance of the arrangement previously referred to, Dr. H went to the home of the patient and delivered the child.

Thereafter, the patient commenced an action against Dr. M claiming that he was responsible for some alleged negligent acts on the part of Dr. H, the substitute physician who actually did the delivery. The nature of the charges is not disclosed in the opinion. Upon the trial the court charged the jury that "the law required the exercise of ordinary care by Dr. M in his personal attention to Mrs. L and also required the exercise of ordinary care by Dr. M in the selection of another physician for her."

There was no proof in the case that Dr. H, the substitute physician, was lacking in those qualifications necessary to treat the case. The court was requested to charge by the plaintiff that any negligence or lack of skill on the part of Dr. H resulting in injury to the plaintiff was chargeable to Dr. M regardless of the care exercised by Dr. M in selecting Dr. H. The jury returned a verdict in favor of Dr. M from which the plaintiff appealed to the Court of Civil Appeals, claiming that the Trial Court was in error in refusing to charge as above stated and for that reason the verdict should be set aside and a new trial granted.

In the first Appellate Court the contention of the plaintiff was sustained and the court squarely held that Dr. M was responsible for the acts of Dr. H. From this ruling the doctor appealed to the Supreme Court of the State where the judgment of the first Appellate Court was reversed and the jury verdict reinstated.

In discussing the situation presented by the facts of the case, the court said:

* Lee vs. More, 211 Southwestern Repts. No. 365.

It is immaterial to the matter of Dr. M's liability for Dr. H's negligence or want of skill under the issues joined here whether Dr. M represented Dr. H to be his partner at the time he proposed sending him. No pleading was filed by the plaintiff alleging that Dr. H was held out to be the partner of Dr. M, nor seeking to hold Dr. M liable as a partner with Dr. H, nor seeking to recover any damages for any misrepresentation of Dr. H's status as a partner. So the question is simply: What was Dr. M's duty, under the law, when plaintiff's husband asked him to speedily dispatch another physician to treat Mrs. L. To our minds this question admits of no answer save the duty of Dr. M to exercise ordinary care in the selection of the physician to be sent, as the jury was instructed by the Trial Court.

The case was clearly decided correctly. It should be noted that there was no claim of abandonment in the case and that concededly the husband of the plaintiff had acquiesced in the arrangements made. The two physicians were clearly independent contractors. There existed between them no partnership. It was not claimed that one was in the employ of the other and there was no sufficient evidence indicating any partnership so far as the handling of the case was concerned. The facts as presented by the record revealed a situation where the legal principle of independent contractors is clearly applicable. This principle makes each physician responsible for his own acts but not for the acts of another physician who takes over the case with the consent and acquiescence of the patient.

Amputation of Leg Following Laceration of Knee

A doctor engaged in general practice of medicine was consulted with respect to certain laceration of the right knee which was sustained by a sixteen-year-old boy. The father gave the history that the boy had been wrestling in a field with some other boy and had fallen on a broken bottle, cutting the knee.

The doctor examined the knee and found that the knee-joint was open through the capsule, the laceration being about 3 inches long. The boy was generally in a filthy condition, with dirty trousers, and the wound at the time was bound up with a dirty handkerchief. Doctor told the boy's father that he should immediately be removed to a hospital but the father refused, saying that he could not afford the expense. The doctor then painted the leg with iodine

and took two stitches on each side of the laceration and inserted a drain into the joint. He attended the boy at his home for several days, upon each of which occasions he applied wet dressings of Dakins solution.

On each of these occasions he advised that the boy should be put in a hospital in order that he might receive suitable treatment. The leg did not improve and on the fifth day the doctor, assisted by another physician who gave an anesthesia, opened the wound and applied new dressings. Two days later, the patient not having improved, was finally taken to a hospital where he was attended by the doctor originally consulted and another physician. The boy remained in the hospital under the care of the two doctors and an infection developed which required curetment on two occasions.

After the boy had been in the hospital for about a month, a consultation was held with another surgeon in which was decided the necessity to amputate the patient's leg about seven inches below the hip joint. Shortly after the amputation the first doctor was discharged from further responsibility.

Some time later a malpractice action was instituted against this doctor charging that it was owing to his negligence that the patient's leg had been amputated. The plaintiff's case proceeded on the theory that the defendant had negligently permitted an infection to develop, which caused blood poisoning and required the amputation. In particular it was contended that on the occasion of the first visit the defendant had neither sterilized nor cauterized the wound.

The case came to trial before a judge and jury and at the end of three days was sent to the jury. A verdict was rendered by the jury in favor of the defendant, exonerating him from the charge of malpractice.

Alleged Improper Anesthetization

In this case the doctor, a general practitioner, was called to the office of his neighbor, a chiropodist, and was asked by the chiropodist to examine the toe of a boy at that time about 16 years of age. Examination by the doctor indicated that the boy was suffering from an ingrown toe nail and that the toe in the region of the nail was swollen and tender. After completing

his examination the doctor told the chiropodist that in his opinion any operative treatment to the ingrown nail should be deferred until the swelling and inflammation had subsided. The doctor thereupon left the office of the chiropodist and heard no more about the case until approximately one week later, when he was called in again and requested by the chiropodist to examine the toe.

The doctor on his examination at this time found that the infection had subsided and that the toe was in such a condition as could safely be operated. In the presence of the doctor the chiropodist thereupon instructed the boy to tell his parents that the toe was now in a condition to have the offending portion of the nail removed, and the following day was set for the operation, contingent, however, upon the approval of the boy's parents.

The next day the doctor was advised by the chiropodist that the boy had returned for the purpose of having the offending portion of the ingrown nail removed, and on that day the chiropodist prepared the boy's foot by washing it with germicidal soap and warm water, drying it with a sterilized towel, and painting the area around the toe with iodine and ether, and then covered the foot with the exception of that part to be operated by a sterile towel. When this had been done the doctor boiled a hypodermic needle for about twenty minutes, inserting it into a syringe and injecting 2 per cent novocaine into the sides of the toe until the toe was anesthetized, but not in the region of the original inflammation. Then the chiropodist removed the offending portion of the nail which had been growing into the toe, placed a sterile bandage on the foot and instructed the boy to return the following day for examination and postoperative treatment.

The following day the doctor received a telephone call from the parents requesting him to come to their home and see the boy. When he arrived there he found the boy in bed complaining of pain with slight swelling of the foot and lower part of the leg. He advised continuous applications of wet dressings of Dakin's solution and told the family that he would return the following day. The doctor returned each day for the next three days and examination on each occasion found that the swelling and tenderness still persisted. He instructed the parents to con-

tinue the application of wet dressings. When, however, the doctor returned the following day and found the condition to be worse he immediately called in a well-known surgeon who, after examining the boy, placed him in a local hospital and thereafter treated him. The surgeon who was called in diagnosed the case as cellulitis and treated him in a hospital with continuous application of wet dressings.

The boy remained in the hospital for about a week at which time the condition had subsided considerably and he was discharged but still remained in the care of the surgeon. About ten days later he was re-admitted to the hospital and an examination at that time disclosed several areas of redness on the left leg in the region of the ankle, together with an abscess on the outer side of the leg. Incision and drainage was instituted and the patient remained in the hospital for approximately three weeks. On the occasion of his discharge from the hospital the cellulitis had disappeared and some time later when the nail again started to grow into the toe he was taken to the hospital and the whole nail was removed.

Thereafter, an action was instituted by the father of the boy, as guardian ad litem, against both the chiropodist and the first doctor. The claim substantially against the doctor was that he injected novocaine into an infected area. The contention of the doctor in the defense of this claim was that he had waited until in his opinion the inflammation and infection had subsided and that the injections he gave were at the base of the nail and nowhere near the site of the original inflammation.

On the first trial the jury after deliberating for approximately six hours reported to the court that they were unable to agree on a verdict and thereupon the court discharged them.

A few months later the case was re-tried and the same claims were advanced by the plaintiff. At the close of the plaintiff's case the court granted a motion made on behalf of the chiropodist to dismiss the complaint as to him because, said the court, there had been no testimony that anything the chiropodist did was indicative of negligence. The case with respect to the doctor was submitted to the jury for their deliberation and after a short consideration of the case they returned a verdict in favor of the defendant.

Counterclaim of Malpractice

In this case the doctor was called to the home of the patient where he found the patient in bed very ill.

The doctor examined the patient and made a diagnosis of pulmonary edema and a myocarditis. He saw him approximately five times for this condition, treating him with hypodermic injections of morphine, atropine, and strychnine. When, however, his condition did not improve after about ten days the doctor advised hospitalization. The patient consented and was taken to a private hospital where he remained for a period of about two months. The treatment administered to him by the doctor during this period of time was complete rest, hypodermics, and regulation of his diet. The doctor saw him approximately every day during his hospitalization and his condition improved to the extent that he was able to return home.

The doctor was thereupon advised by the daughter of the patient that her father had another doctor and would no longer

require his services. The doctor thereupon sent bills to his patient for some time but they never were paid and he finally turned the matter over to a collection agency which brought suit on behalf of the doctor for the unpaid bill.

In answer to this suit the patient interposed a counterclaim in which he charged that the defendant had been guilty of malpractice in the care of the case and demanding the sum of \$1,000 as damages. The precise nature of the patient's claim of malpractice was never learned for it was not specified in the pleadings and at the time the case was reached for trial neither the patient nor his attorney appeared to contest the doctor's claim and the court thereupon dismissed the counterclaim of malpractice and granted the doctor judgment for the amount sued.

It was obvious that the claim of malpractice had been merely inserted into the case for the purpose of delay and for the purpose of attempting to cause the doctor to abandon his suit to recover for his fee for professional services.

THE UNKINDEST CUT OF ALL

While the government's delegated alphabet committees are avowedly striving to raise the cost of everything that the consumer must buy, there is one outstanding exception, notes the *Journal-Lancet*, of Minneapolis. The manufacturer, wholesaler, and retailer in every line of industry is protected by price-fixing codes and anti-chiseling regulations that establish inescapable prices for their goods. The one exception is the physician.

Public relief must, of necessity, contemplate the payment of these established and so-called fair prices by agencies that furnish food, shelter, and raiment in order to fit in with the program of national rehabilitation. When it comes to the physician, however, he is asked to take a cut. It is reported that the contact officers who are organizing medical relief units in the various states have suggested a 30 per cent and in some cases a 50 per cent discount of that which was

previously set up and conceded to be a reasonable fee schedule. The President has already made a basic commitment to "operation for profit." How does this pronouncement fit in with the attitude toward our profession when it is generally conceded that the operating expenses of a medical practice in the first place is 50 per cent of gross and in times like these even 70 per cent? The war department comes along with a request that members of the medical profession give physical examinations, inoculations and vaccinations to C.M.T.C. candidates without any charge whatever, so that does not answer the question. It has become a habit to expect it.

We're a patriotic bunch, all right, and willing to go the limit in assisting our government and our fellow men but it appears that our material needs are often forgotten. It is altogether too complimentary to assume that the medical profession alone can live on adulation.

A DEAD-LINE ON DEADBEATS

More and more county medical societies are establishing bureaus for listing habitual deadbeats, along lines similar to those employed by the Wichita (Kansas) Medical Credit Bureau, which is maintained by the Sedgwick County Medical Society, states the county's *Medical Bulletin*.

Physicians of Washington, Iowa, recently an-

nounced in the local press that they are keeping up to date a confidential listing of patients who are known to have the habit of switching doctors to escape paying their bills.

Some 6,000 names are now on file in the executive office of the S.C.M.S. Members are urged to make use of the information in these files.

Books

BOOKS RECEIVED

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Essentials of Histology Descriptive and Practical for the Use of Students—By Sir I. Sharpey Schafer. Thirtieth Edition. Edited by H. M. Cleeton. B. Sc. Octavo of 618 pages illustrated. Philadelphia: Lea & Febiger, 1934. Cloth \$5.00.

A Text Book of Histology Functional Significance of Cells and Intercellular Substances—By I. V. Cowdry. Octavo of 503 pages illustrated. Philadelphia: Lea & Febiger, 1934. Cloth \$5.50.

The Anatomy of Surgical Approaches—By I. C. Kellogg. M.D. 12mo of 134 pages illustrated. Baltimore: William Wood & Company, 1934. Cloth, \$1.50.

Physical Diagnosis—By Richard C. Cabot, M.D. Eleventh Edition. Octavo of 540 pages illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$5.00.

Electrocardiography—By Chauncey C. Maher. M.D. Octavo of 250 pages illustrated. Baltimore, William Wood & Company, 1934. Cloth \$4.00.

A Text Book of Medical Psychology—By Ernst Kretschmer, M.D. Translated by I. B. Strauss. M.D. Octavo of 274 pages illustrated. New York: Oxford University Press, 1934.

Applied Anatomy—By Gwylm G. Davis, M.D. Ninth Edition. Edited by Geo. P. Muller, M.D. et al. Quarto of 717 pages illustrated. Philadelphia, J. B. Lippincott [c. 1934]. Cloth \$9.00.

Mortality Among Patients With Mental Disease—By Benjamin Malisberg. Phi D. Octavo of 234 pages. Utica, N. Y., State Hospitals Press, 1934.

Allergy and Applied Immunology—By Warren T. Vaughan. M.D. Second Edition. Octavo of 420 pages illustrated. St. Louis, C. V. Mosby Co., 1934. Cloth \$5.00.

Diabetic Manual for Patients—By Henry J. Jolin, M.D. Second Edition. Duodecimo of 232 pages. St. Louis, C. V. Mosby, 1934. Cloth \$2.00.

Synopsis of Genitourinary Diseases—By Austin I. Dodson, M.D. Duodecimo of 275 pages illustrated. St. Louis, C. V. Mosby, 1934. Cloth, \$3.00.

Rules for Recovery from Tuberculosis—By Lawson Brown, M.D. Sixth Edition, Revised. Sexdecimo of 275 pages. Philadelphia, Lea & Febiger, 1934. Cloth \$1.75.

Cataract. Its Etiology and Treatment—By Clyde A. Clapp. M.D. Octavo of 254 pages illustrated.

Philadelphia Lea & Febiger, 1934. Cloth \$4.00.
Sex Hygiene What to Teach and How to Teach It—By Alfred Worcester. M.D. Octavo of 134 pages. Springfield, Charles C. Thomas [c. 1934]. Cloth, \$2.50.

Hygiene for Freshmen—By Alfred Worcester, M.D. Octavo of 151 pages. Springfield, Charles C. Thomas [c. 1934]. Cloth \$1.50.

Institutional Care of Mental Patients in the United States—By John Maurice Grimes. M.D. Octavo of 138 pages. Chicago, J. M. Grimes [c. 1934]. Cloth, \$3.00.

An Activity Analysis of Nursing—By Ethel Johns, R.N. and Blanche Pfefferkorn, R.N. Duodecimo of 214 pages. New York, Committee on the Grading of Nursing Schools, 1934. Cloth \$2.00.

Nursing Schools Today and Tomorrow—Final Report of the Committee on the Grading of Nursing Schools. Duodecimo of 268 pages. New York: Committee on the Grading of Nursing Schools, 1934. Cloth \$2.00.

A Manual of the Practice of Medicine—Prepared especially for students. By A. A. Stevens. M.D. Thirteenth Edition. Revised. Duodecimo of 685 pages. Philadelphia: W. B. Saunders, 1934. Cloth, \$3.50.

Practical Obstetrics for Students and Practitioners—By P. Brooke Bland. M.D. and Thaddeus L. Montgomery, M.D. Second Edition. Octavo of 730 pages illustrated. Philadelphia, F. A. Davis Company, 1934. Cloth, \$8.00.

The Patient and the Weather—By Wm. F. Petersen. M.D. assisted by Margaret F. Milliken. S.M. Volume III. Mental and Nervous Diseases. Quarto of 375 pages illustrated. Lithoprinted. Ann Arbor, Edwards Brothers, 1934.

The Jew in Science—By Louis Gershenfeld. Duodecimo of 224 pages. [Philadelphia: Jewish Publication Society of America, 1934. Cloth, \$2.75.]

The B. C. G. Vaccine—By A. Neville Irvine. Octavo of 66 pages. London, Oxford University Press, 1934. Cloth, \$1.75.

Gynecology—By Brooke M. Ansbach. M.D. Fifth Edition, revised. Octavo of 832 pages illustrated. Philadelphia: J. B. Lippincott [c. 1934]. Cloth \$9.00.

The Life of Sir Robert Jones—By Frederick Watson. Octavo of 327 pages illustrated. Baltimore, William Wood & Company, 1934. Cloth \$3.75.

BOOKS REVIEWED

Sculpture in the Living Rebuilding the Face and Form by Plastic Surgery—By Jacques W. Maliniak, M.D. Octavo of 203 pages illustrated. New York: Lancet Press, 1934. Cloth \$3.00.

This book of Dr. Maliniak's does not confine itself to purely cosmetic questions. It covers the entire range of disfigurement from its functional as well as esthetic aspects. It is concerned with many commonly encountered psychic phenomena and appraises the factor of disfigurement in social maladjustment and economic failure and evaluates potentialities of corrective surgery as an aid to the mental and economic rehabilitation of the disfigured.

Plastic surgery is presented to the physician and to those especially interested in the field of plastic surgery, and it also presents a strong appeal to the layman who is either subjectively or objectively interested. In a very easily comprehensible manner the indications for plastic repair are outlined and its limitations are given. Yet in no sense can this be termed a textbook for medical students or even for students of plastic surgery. Rather than this the book is a guide to the interested layman to show him what plastic surgery can do for him. Ordinarily indications for surgery are fixed upon definite findings. In plastic surgery and in also that part of it called cosmetic surgery the psychic and neurogenic elements which form a basis for indication sum up to a total which places the indications for plastic surgery in a very different category from the indications for operation as medical men are wont to recognize.

To the average physician, the book should be a fund of knowledge to place him in a position to advise his

or, hardly the last written statement published by the late Wendell C. Phillips. To quote him gives this book its endorsement. Phillips says: "The education of the public in medical questions has been an accepted principle of organized medicine for a number of years. In the case of plastic surgery, the comparative newness of this specialty and the absence of an authoritative national body for the consideration of its problems have conspired to keep the public in ignorance of the truth about surgical reconstruction and to leave the dissemination of publicity on the question in the hands of charlatans and dubious medical practitioners."

This book is charmingly written is very instructive, interesting as well as authoritative.

S. J. KOPFTZKY

Medical Clinics of North America Published every other month by the W. B. Saunders Company Philadelphia and London. Per Clinic Year (6 issues) cloth, \$16.00 net, paper, \$12.00 net.

Vol 17, No 1, July, 1933

(New York Number)

The New York number of the *Medical Clinics of North America* for July, 1933 contains a noteworthy contribution by Cc.

the anatomy, the excellently illustrated carcinoma of the Mesentherial of case of spontaneous course of essential neoplasm of the

of the stomach and splenic flexure. Blumgarten discusses spontaneous hypoglycemias in endocrinopathies. This subject certainly requires further elucidation. Bullowa highly favors the use of avertin for the delirium in pneumonia.

An excellent discussion on skin tumors with special reference to precancerous dermatoses and the group of mycosis and related conditions was contributed by Highman. Mackie has a valuable contribution on non-tropical sprue with an excellent bibliography. Tenney and Goldstein discuss the mental symptoms of pernicious anemia and advocate the use of liver therapy for their relief.

Harkavy believes in a thorough investigation of the nasal sinuses for the treatment of persistent or return infections of the lung, urticaria, and asthma. Epstein speaks of favorable results with the use of gold tribromide in pertussis.

A splendid paper by Schwartz and Jezer on Stokes-Adams syndrome is the outstanding contribution. Discussion of the four different types and their respective treatments is given.

Winkelstein discusses the inter-relationships of abdominal symptoms and coronary artery disease and the differential diagnosis between thoracic and abdominal conditions in the angina syndrome. Friedenson's discussion of diuretics in advanced cardiac insufficiency is important.

An excellent contribution from Beth Israel Hospital by Weiss, Grossman and Feinstein discusses the differential diagnosis of hypertension, particularly with reference to surgical kidney pathology, nephritis, and nephrosclerosis. Goldbloom lays considerable stress on the diagnostic importance of blood volume and cardiac output studies in borderline cases of thyrotoxicosis, and splendidly illustrates this with a case of vegetative nervous imbalance.

Vol. 17, No. 2, September, 1933
(Chicago Number)

The September number of the *Medical Clinics of North America* contains a symposium on blood dyscrasias. The rationale of x-ray therapy in leukemia is excellently presented. Cases of agranulocytosis, streptococcus viridans sepsis without endocarditis and accompanied by aplastic anemic blood picture, and acute leukemia are presented by Tice. Hemophilia, polycythemia and aplastic anemia, anemias of gastro-intestinal origin are discussed by other contributors.

Foley stresses the importance of cholecystography in jaundice and shows that a positive visualization of the gallbladder in the presence of jaundice speaks for intra-hepatic disease.

Cinchophen poisoning is thoroughly discussed clinically and pathologically by Carroll. The reviewer is happy to note that his own observations on cinchophen poisoning have been amply corroborated by these careful observers.

Other contributions include tuberculides of the skin, the acidotic diet treatment of chronic urinary infections, and the treatment of coronary thrombosis by oxygen inhalation.

Vol. 17, No. 3, November, 1933
(Philadelphia Number)

Among the contents of the Philadelphia number of the *Medical Clinics of North America* is an excellent description of the encephalitis epidemic of St. Louis, 1933. Pituitary endocrine disturbances, periarteritis nodosa, and coronary thrombosis simulating acute surgical abdomen are also well expounded.

Of great interest is the discussion of aleukemic reticulosis, Dr. Myer Solis-Cohen's stressing the value of quinine in large doses in pneumonias of infancy and childhood, and an account of the unusual condition of ocular pemphigus.

The number as a whole is an exceedingly good one from the point of view of the general practitioner, and there are some sound discussions on hemolytic jaundice, the anemias, multiple sclerosis, relationship of psychology to medicine, basal lung tuberculosis, hyperthyroidism, hypertensive encephalopathy, and congenital heart block.

Vol. 17, No. 4, January, 1934
(Cleveland Clinic Number)

The Cleveland Clinic number contains many satisfactory articles. Haden discusses the clinical factors in the production of anemia and their treatment. He also gives a differential diagnosis of chronic hypertrophic and chronic atrophic arthritis, outlines a form of study and treatment in these conditions. Hartsock stresses the investigation and treatment of gastro-intestinal and nutritional factors in the treatment of chronic atrophic arthritis. Ernestine mentions that cardiac manifestations may be the first evidence of hyperthyroidism, discusses the use of quinidine in auricular fibrillation, the importance of rapid digitalization in severe heart failure after thyroid removal, and stresses that hyperthyroidism is not the sole cause of the cardiac state in hyperthyroidism.

Tucker discusses the management of the parathyroid tetany and its clinical phases, including the use of very large doses of calcium. McCullagh discusses hypogonadism in the adult male following bilateral herniorrhaphy and gives a differential diagnosis from hypothyroidism. He mentions improvement with the use of Androline, a comb growing promoting substance from male urine. John discusses spontaneous hyperinsulinism and gives his reasons, with an illustrated case, for the use of low carbohydrate with high fat diet together with 10 units of insulin a half hour after meals. In the discussion of diabetes, he insists on determinations of the blood sugar three times daily before meals for the intelligent adjustment of both diet and insulin.

Netherton advises the use of sodium thiosulphate, large doses of adrenalin, and hypertonic glucose for the treatment of neosalvarsan encephalitis. Ruedemann's article on the ocular muscles is well worth while reading. The proper study, differential diagnosis and treatment of neurosis of the digestive tract are discussed by Hartsock. The importance of esophagoscopy in the early recognition of carcinoma of the esophagus is stressed by Collins.

Tucker gives some observations on chronic ulcerative colitis and mentions the use of malt extract, codliver oil, yeast extract, iodine, autogenous vaccine, and ileostomy. The various causes of non-nephritic albuminuria are given, and the clinical types of Bright's disease are discussed by McDonald. Particular stress is laid on the urea clearance test as a prognostic sign. Nichols and Shiffert emphasize the importance of proper x-ray studies for the diagnosis of renal tumors, especially in the absence of urinary symptoms. Netherton shows some splendid results with the use of intravenous injections of typhoid vaccine in tinea sycois.

Vol. 17, No. 5, March, 1934
(New York Number)

The March number of the *Medical Clinics of North America* contains a clinic of three cardiac cases by Brooks, several papers on hyper- and hypothyroidism, tests of renal function, diet and anemia in Bright's disease, a paper by Bela Schick on abnormal nutritional states in children and an excellent discussion by W. C. Phillips on problems in impaired hearing.

There is a thorough discussion of perforated peptic ulcer and its differential diagnosis by I. W. Held and A. A. Goldbloom. The significance of salt in the treatment of Addison's disease, dehydration and medical shock is noteworthy. A very stimulating paper is the one on angiospastic diathesis by L. Lichtwitz.

The number ends with a symposium on diseases of the peripheral vascular system with a discussion of the diagnosis, medical and surgical treatment, arteriography, apparatus and technic for the study of these diseases.

M. A. RABINOWITZ

Vol. 17, No. 6, May, 1934
(Index Number)

Sloan discusses temporal tumors, giving as symptoms, "smelling bad odors," dream states, convulsive seizures, uncinete attacks, disturbances in taste, deafness, visual field defects, hemiparesis, cerebellar signs, and ipsilateral dilatation of the pupil.

Brawley mentions eye irritations due to hair dyes, mascara, perfume, cold creams, astringents and lotions. Dermatitis due to the use of aniline dyes may cause a reaction as early as two hours or as late as twelve days. DeTakats advises a test with ergot in juvenile diabetes and states that if the galactose tolerance curve is significantly depressed, then bilateral splanchnic section is indicated in severe cases in the young.

Meyer describes a case of Papet's disease of thirteen years duration without any deformities. Coogan reports pulsus bigeminus in healthy individuals under emotional strain, temporarily restored to normal by atropine, and permanently restored to normal after the end of the emotional strain.

Keeton mentions that some cases of Parkinsonism have associated hyperthyroidism. He stresses the fact that a hyperthyroid patient should not lose weight on a diet containing an excess of 15 per cent above the basal caloric need.

Portis discusses the preoperative laboratory examinations in gallbladder disease, as well as preoperative and postoperative care.

Coggeshall reports a case of malignant neutropenia where x-ray gave a temporary high leukocytosis, but he believes that increase of leukocytes after x-ray does not always mean a good result and may be followed by fatal outcome.

Heinz gives an excellent differential diagnosis between sigmoid carcinoma and diverticulitis. Ricketts adds five cases of toxic necrosis of the liver due to cinchophen, to the already voluminous literature. He substantiates all the findings and repeats the warnings made by the reviewer in the *Medical Clinics of North America* for January, 1929, and in subsequent papers.

M. A. RABINOWITZ

VEGETATIVE DISTURBANCES OF CEREBRAL ORIGIN

JOSEPH H. GLOBUS, M.D.

From the Neurological Service and the Division of Laboratories, the Mount Sinai Hospital New York City

The autonomic nervous system with its two subdivisions, the sympathetic and parasympathetic, was until recent years considered to be somewhat restricted in its functions. It was thought, as its name suggests, that it provided for functional independence or autonomy of the several vital internal structures of the organism. Of late, however, it has become obvious that its influence is much wider and more important. It provides a mechanism for orderly and co-ordinate actions of the internal organs such as the viscera, glands of internal and external secretion, the vascular, respiratory, genital, and muscular systems. Evidence is also accumulating to show that it contributes to the orderly action of the skeletal muscles. In this fashion the assimilative and eliminative processes, cardiovascular, respiratory, and other similar mechanisms, as well as the voluntary muscle function, are synergized and synchronized to be readily mobilized for adjustment to changes in internal and external environment.

The regulating influence of the autonomic nervous system, particularly over the so called vegetative processes, is obviously essential to the balanced life of the organism. It is because of this feature that the autonomic system with its central and peripheral portions came to be known as the *vegetative nervous system*. Thus, the modifying term *vegetative* is applied to that part of the nervous system which regulates the organs concerned with the secretion and excretion as well as the motility or contractibility of the various viscera. Hence, all functions of the organs and structures under the control of this system (possibly including muscle tone also) are rightly designated as *vegetative*.

The normal vegetative functions are, therefore, those which maintain continuity of the orderly life of the organism. They include the metabolic, contractile, secretory, and excretory activities. Many of these activities under certain conditions are carried out independently by the respective organs under the direct control of the intrinsic or peripheral portions of the autonomic nervous system. The co-ordination of such activities is, however, supervised by nerve centers in various parts of the supersegmental system. It is in the supersegmental system that we find the higher regulating vegetative mechanisms, and, as we pass from the medulla through the pons and midbrain and enter the *diencephalon*, we reach a small segregated area in which is situated a centralized series of co-ordinating vegetative nuclei.

THE DIENCEPHALON

The *diencephalon*, also known as the *interbrain*, is established early in the development of the central nervous system as a distinct subdivision (See Fig 1). A glance at the accompanying diagram will show the crucial location it occupies in the fully developed brain (See Fig 2). It will be seen that it is at the cross roads between the *telencephalon*, the most recently developed part of the central nervous system, and its more ancient parts—the lower portions of the brain stem and the spinal cord. In this location it holds a key position between the initiating and inhibiting centers in the cerebral cortex and lower subservient functional areas. In this fashion it brings the vegetative system in relation with the psychic zones of the brain on the one hand, and on the other, portions

of the brain in which reside simpler subordinate reflex centers.

The diencephalon includes among its

Fig. 1.—Drawing showing an early stage in the development of the diencephalon (D).

Fig. 2.—Drawing showing the location of the diencephalon in relation to other parts of the brain.

several parts the *hypothalamus* which is of particular interest here. The hypothalamus contains several circumscribed aggregations of cells, so-called *nuclei*, which include the nuclei of the tuber cinereum, the supra-optic nuclei, nuclei of the mammillary bodies, and the paraventricular nuclei. (See Fig. 3.) These nuclei were recently subgrouped into an *anterior subdivision* which includes the nuclei of the tuber cinereum and supraoptic nuclei and a *posterior subdivision* which consists of the paraventricular nuclei and those overlying the mammillary bodies. The anterior division is regarded as *parasympathetic* in function because of the relationship of its nuclei to the vagus and pelvic nerves which belong to the cranio-sacral (parasympathetic) outflow, while the posterior division is considered as a supersegmental center in the thoraco-lumbar outflow of the *autonomic* system.

Vegetative Dysfunctions. It is now fully accepted that lesions involving the diencephalon often result in vegetative dysfunctions, chief among which are disturbances in water balance; anomalous fat distribution; abnormal alterations in primary and secondary sex functions and morphology; disturbances in heat regulation, vasomotor mechanism, sleep, intestinal peristalsis, and appetite. While in the exceptional instance disease of the diencephalon may express itself in a single vegetative disturbance, it is more common to find that a disease, even when localized in the hypothalamus, is more apt to result in dysfunctions which may assume a variety of constellations of signs or symptoms or so-called syndromes.

ILLUSTRATIVE CASES

CASE 1. History.—A girl, aged six years, was apparently well until six months before admission to the hospital. She then became markedly constipated, slept poorly, was restless, lost her appetite and experienced constant thirst. The diagnosis of diabetes was made, and the child was treated accordingly. With the increase of thirst and increase of water intake, there was an increase in volume and frequency of urination. The child was losing strength and would frequently complain of fatigue; she gave up playing and became confined to bed.

Neurological Data. The child was undersized with a profuse growth of lanugo hairs all over her body. There was ptosis of the right eyelid and external strabismus of the right eye. The left pupil was larger than the right. Both pupils reacted to light and during accommodation. There was a left-sided hemiparesis.

Course and Anatomical Findings. The diag-

nosis of neoplasm involving the posterior lobe of the pituitary body encroaching upon the right crus cerebri was made. The patient was subjected to an exploratory craniotomy which was followed by death. At necropsy a cyst was found at the base of the brain. It covered the optic chiasm to which it was adherent and filled the entire interpeduncular space. (See Fig 4.) Its bulging inferior and exposed surface was prolonged into a funnel shaped process which seemed to be continuous with the pituitary body. The latter was extremely small in size, compressed and was lodged in a shallow and eroded sella turcica. The superior surface of this mass was firmly implanted in the substance of the brain, and the tuber cinereum and the mammillary bodies could not be identified since the floor of the third ventricle was stretched and flattened by the tumor mass.

Comment. The constellation of signs and symptoms of vegetative dysfunction in this case includes polydipsia, polyuria, retention of lanugo hair, asthenia, and obstipation. Of particular significance, however, are the manifestations of disturbed balance in water metabolism. The disruption of the floor of the third ventricle, caused by the craniopharyngioma, is in keeping with the belief that the region of the tuber cinereum is the seat of a regulating center for such vegetative functions.

CASE 2 History.—A boy, three and a half years old, was admitted to the hospital for the first time on December 29, 1930. At that time he suffered from headache over a period of three months and vomiting of one month's duration. More recently he became thirsty and would urinate frequently.

Neurological Data. Examination revealed hemiparesis with a positive Babinski sign, diminished abdominals on the right side, and in complete primary optic atrophy on the left side. X ray of the skull showed deformity of the sella with erosion and pointing of the posterior clinoids several small concretions in the sella and two small calcifications above the sella.

Course and Anatomical Findings. The patient was operated upon and a suprasellar, Rathke's pouch, cyst was found. The entire suprasellar portion of the tumor was removed. Following the operation the temperature rose to 106° F. It came down the following day, and the patient passed through a satisfactory convalescence. Following his return home there was still evidence of polydipsia and polyuria. He would take about ten glasses of fluid and voided an equal amount of urine. This gradually subsided and a note on December 7, 1930, a year later, read "The patient no longer has diabetes insipidus." The child was readmitted to the hospital on April 3, 1933, with a history of acute pain in the right ear which developed in the course of measles and was followed by the development of the picture of lateral sinus thrombosis. The internal jugular vein was ligated. The patient did not do well and died three days after admission to the hospital. Necropsy revealed a large cyst occupying the entire interpeduncular space. (See Fig 5.) It

extended beyond that space forward to the under surface of the cerebral hemispheres. It was adherent to the walls of the sella and at one point showed a defect.

Comment. This case again illustrates the occurrence of signs of diabetes insipidus in connection with lesions in the floor of the third ventricle. It is, however, still more significant because of the fact that

Fig. 3.—Drawing showing the distribution of some diencephalic nuclei (after Kuntz)

Fig. 4.—Ventral surface of the brain (Case 1) showing cystic tumor (craniopharyngioma) in the interpeduncular space—floor of the third ventricle

the signs of diabetes insipidus disappeared after the tumor was partially opened and pressure on the floor of the third ventricle was released. No less significant is the observation that with only partial removal of the tumor the patient was comfortable for a period of two years; and were it not

for the ear infection, it is quite possible that the patient would have continued to do well. It would seem that the less radical step in the case of craniopharyngeal cysts is a procedure of choice.

CASE 3. History.—A boy, ten and a half years of age, was seen but once in the Out-patient Department of the hospital. He was unusually obese with excessive fat about the hips, breasts, and genitalia. The formation of scrotum suggested that of the vulva. He gave the impression of Froehlich's syndrome. He was not seen again until he was brought to the hospital with a brief history and signs of acute appendicitis. An inflamed appendix was removed. Soon after operation he began to complain of headache and revealed a rigid neck.

Neurological Data. There was advanced bilateral papilledema with retinal hemorrhages. The blood pressure was 150 systolic and 115 diastolic. The patient was drowsy and at times stuporous. Roentgen-ray examination of the skull was unsatisfactory.

Course and Anatomical Findings. Because of manifestations of Froehlich's syndrome coupled with the papilledema, headache and advancing drowsiness, the diagnosis of a cerebral neoplasm, probably suprasellar in location, was made. At operation a cyst was encountered and was excised. The patient remained in good condition for several hours, but eight hours later his temperature rose abruptly to 105° F., dropped to 103.4° F., but rose again just preceding death which occurred seventy hours after operation. At necropsy the remains of the cyst were found. (See Fig. 6.) There was no gross surgical damage to the brain which could account for the elevation of temperature or the rapid death.

Comment. The abnormal obesity of the patient and the poor development of the secondary sex characters are a common finding with tumors in the floor of the third ventricle. It is also quite probable that hypertension present at this age in a boy who displayed other vegetative dysfunctions may also be traced to a lesion in this location. The sudden rise in temperature may find its explanation in the dislocation of the floor of the third ventricle as the result of the sudden collapse of the cyst. The above views are strengthened by the fact that the pituitary body was found to be normal.

CASE 4. History.—A man, 46 years of age, entered the hospital complaining mainly of failing vision during the past seven years. At adolescence it was noticed that his genitalia were rather small and that the left testicle was incompletely descended. His pubic and axillary hair was scanty, and its distribution was of the feminine type. His sex life was rather active until the age of 32. About this time and ten weeks after marriage, there appeared a decided decline in both libido and potency, and within one year he became totally and permanently im-

Fig. 5.—Ventral surface of the brain (Case 2), showing cystic tumor (craniopharyngioma) in the interpeduncular space (as in Fig. 4).

Fig. 6.—Ventral surface of the brain (Case 3), showing cystic tumor (craniopharyngioma) in the interpeduncular space (as in Fig. 4).

potent. Six years ago he noticed impairment of vision in the right eye which later became totally blind. During the past year and a half, vision in the left eye became impaired, too. With this there was occasional headache.

Neurological Data.—The patient was short and obese and hypopituitary in type. He had unusually small hands and feet, a protuberant abdomen, well developed female type breasts, marked scarcity of hair, and an absent left testicle. There was diminution of sense of smell on the right. His pupils were irregular and unequal (right larger than left); the right pupil reacted sluggishly to light. There was bilateral optic atrophy with total loss of vision of the right eye, and temporal loss of vision in the left.

Course and Anatomical Findings.—The diagnosis of pituitary neoplasm was made, and its removal was attempted. The pituitary region was exposed through a right frontal approach, and the surgeon removed part of the tumor. On completion of the operation the patient's temperature suddenly rose to 105° F., dropping the following day to 102° F. It rose again to 106° F. on the third postoperative day, shortly before death.

Comment: In this case the necropsy revealed a large tumor mass (see Fig. 7), part of which was removed by the surgeon. The tumor had elevated the floor of the third ventricle and, in so doing, had thinned it out, causing disruption of its structure. It is fair to assume that this dislocation of the floor of the third ventricle with the incident disruption of its structure was responsible for the vegetative dysfunctions in this case. The latter included: (1) disturbance in the development of the secondary sex characters, (2) the loss of potency, (3) abnormal distribution of fat and (4) the inadequate development of hair.

CASE 5 History.—A woman of 32, on entering the hospital, gave a history of intermittent headache, amenorrhea, sterility, obesity, impaired vision, and development of coarse facial features. Her menstruations began at the age of 15 and were regular until the age of 22. Soon after marriage, at the age of 22, her menstruation became at first irregular and scanty and, three months later, ceased completely and permanently. At the same time she began to gain considerable weight, so that in the course of the last ten years she has gained sixty pounds. There were no pregnancies. For the past two years she noted diminution of vision in the left eye. For some time she began to experience considerable thirst and would drink large quantities of water. During the past six days headache, which was at first intermittent, became very intense. Vision in the left eye became more impaired. Vomiting and drowsiness set in shortly before she was brought to the hospital.

Neurological Data. The patient was obese. There was convergent strabismus, diminished acuity of vision in the left eye, ptosis of the

left eyelid, exophthalmos on the left, right homonymous hemianopsia, and bilateral choked discs.

Course and Anatomical Findings. The objective findings supported by positive x-ray findings, which included enlargement of the sella turcica, irregularity of its floor, and destruction of the posterior clinoids, led to the diagnosis of pituitary tumor. At operation a large pituitary cyst was found. It ruptured, emptied about 40 c.c. of brownish fluid, and, as it collapsed, disappeared from view. Following the operation there was sudden rise of temperature. The patient declined slowly and died on the third day after operation. Necropsy disclosed a markedly disturbed hypothalamus. (See Fig. 8.)

Comment. In this case we have a situation very similar to that noted in the pre-

Fig. 7.—Extensive tumor at the base of the brain arising in the interpeduncular space (Case 4).

Fig. 8.—Sagittal section of the brain (Case 5), showing elevation and thinning of the floor of the third ventricle by a large tumor mass (solid craniopharyngioma).

vious case, except that the alterations in sex characters in this instance occurring in a female expressed themselves in amenorrhea and sterility, which may safely

be attributed to the disease of the diencephalon.

CASE 6 History.—The patient was a 25-year-old married woman who was apparently well until five years prior to her admission to the hospital. At that time she noted that she was no longer menstruating. She became more or less undernourished and underweight. She occasionally suffered from headache. One year ago she shaved the hair under the axilla, and since then no growth of hair occurred there; there was always a little hair over the genitalia. More recently she developed some impairment of the extrinsic eye muscles and would vomit occasionally.

Neurological Data The patient was a rather undersized female with moderate acromegaloïd features. There was marked scarcity of hair over the pubes and in the axilla. (See Fig. 9.) Bilateral optic atrophy, diminished vision in the left eye, and a weakness of the left internal rectus muscle were the main neurological findings.

Course and Anatomical Findings. The diagnosis of a pituitary neoplasm was made, but because of a marked secondary anemia it was thought advisable to try the effects of radiotherapy. This treatment resulted in but doubtful temporary improvement, and somewhat later, as vision continued to diminish, she was readmitted to the hospital. In the course of a transfrontal craniotomy a tumor was found in the proximity of the optic chiasm. Its capsule was incised, and the contents of the tumor were removed. Following the operation and for a period of three weeks the patient ran a most unusual type of temperature curve (See Chart I) which was regarded to be hypothalamic in origin. Then moderate improvement set in, and some vision was regained. At first the patient steadily gained weight, and the blood count showed improvement. She returned home but soon began to complain of headache, vomited frequently, became somnolent, ran an irregular temperature, and finally became drowsy, disoriented. She was readmitted to the hospital with signs of meningeal irritation and died six weeks later. The necropsy showed some remnants of the tumor in the region of the tuber cinereum, which was completely disorganized. Along side of this area there was an abscess in the process of healing.

Comment. This case illustrates again that a lesion in the region of the tuber cinereum is provocative of alterations in the secondary sex characters, alterations in the essential sex function. It further demonstrates that an extension of such a lesion which occurred during the operative procedure may, and often does, cause the disruption of the temperature regulating mechanism with the resultant temperature-pulse discord to which attention was already directed by the author in collaboration with Strauss.

CASE 7. History.—A woman, aged 57, began to show changes in personality during the year

Fig. 9.—The patient on first admission (Case 6). Note complete loss of pubic hair

Fig. 10.—Gummatous lesion in the tuber cinereum (Case 8).

preceding admission to the hospital. She became forgetful, irritable, somewhat euphoric, and voracious. During the last three months she slept most of the time and ate constantly during waking moments.

Neurological Data. The patient, when not asleep, was dull and apathetic. She was disoriented and confused. The neurologic signs were few and included irregularity and inequality of the pupils, slight weakness of the right side of the face, deviation of the tongue to the right,

the optic chiasm in the region of the tuber cinereum and mammillary bodies.

Comments. It is significant that symptoms, such as presented in this case, without the present day's knowledge of the functional significance of the diencephalon would not have been regarded as of a localizing value. Disturbance in appetite, sleep, temperature, and pulse may now

Chart I.—Temperature and pulse rate curves (Case 6). Note the discord between pulse and temperature. When the latter is elevated, the pulse rate does not follow and at times drops.

Chart II.—Temperature and pulse rate curves (Case 7). (Compare with Chart I.)

and depressed deep reflexes. From the day of admission until the day of discharge the patient's temperature was elevated. It fluctuated between normal and 103° F. The rises and falls occurred irregularly and were not followed by a corresponding rise in the pulse rate. (See Chart II.)

Course and Anatomical Findings. The scarcity of objective findings, the slowly progressive clinical course, the peculiar mental picture, and the vegetative disturbances including the temperature-pulse discord led to the diagnosis of brain tumor with the probable location in the floor of the third ventricle. At necropsy a tumor was found at the base of the brain, just behind

rightly be considered as manifestations of a focal brain disease.

CASE 8. History.—A man, 48 years of age, was hemiplegic since infancy and mentally retarded since childhood. Five months before admission to the hospital he began to lose his eyesight and was troubled by excessive thirst and frequent urination. Apparently pituitary dysfunction was suspected, and he was given pituitary extract. He responded to treatment by slight improvement in vision and a decided diminution of thirst and urination. As soon as treatment was interrupted—five weeks later—his symptoms promptly re-

appeared. Now return to the previous medication affected his symptoms but slightly.

Neurological Data. The main positive findings included: (1) left-sided hemiplegia, (2) bi-temporal hemianopsia, (3) pallor of the optic discs, (4) pupils unequal and poorly reacting to light. The blood and cerebrospinal fluid and Wassermann tests were positive (4+).

Course and Anatomical Findings. In view of the visual field findings, the polydipsia and polyuria, a pituitary cyst was suspected. The patient declined rapidly and died without operative interference. Necropsy disclosed a syphilitic lesion, gummatous in character, in the floor of the third ventricle. (See Fig. 10.)

Comments. This case illustrates that lesions other than neoplastic but situated in the hypothalamus are equally capable of provoking signs and symptoms of vegetative dysfunction.

GENERAL COMMENT

It is rather significant that in all of the cases of the series reviewed, a lesion in the diencephalo-hypophyseal region was diagnosed. In arriving at a diagnosis, the strictly neurological manifestations, point-

ing to the proximity of the disease process to the interpeduncular space—and hence the tuber cinereum—and the roentgenologic demonstration of calcific bodies in, or above, the sella turcica were, of course, important guides. But the presence of vegetative dysfunctions was a determining factor. No less significant is the fact that in every instance a lesion in the hypothalamus was verified by anatomical studies, and that in the majority of the instances the hypophysis was found intact. This would seem to substantiate the views held with regard to the hypothalamus that it serves as an important center controlling the interacting vegetative functions.

SUICIDE OF ADOLESCENTS

The peculiar state of mind of the adolescent explains why so many young people take their own lives, in the opinion of a French physician who has written an article about it. As told by the Paris correspondent of the *A.M.A. Journal*, Dr. Gilbert Robin believes that adolescence is the period of life in which the parents should never use harsh measures in the form of commands or injunctions. There is revolt and an inevitable struggle on the part of the recipient, whose personality at this period is too strong for the world, which is opening its doors to assimilate him.

The point of view of the adolescent is not that of the adult. The adolescent believes himself to be a hero and hence there arise misunderstandings between him and the adult. According to Robin, it is the contact of this intense personality, which considers that it cannot live in the adult world and seeks any means to avoid it, which plays the leading part in suicides of the adolescent. In some cases the contrary occurs. The personality is groping to find its place in organized society and it is at the end of a fruitless search. Others become too introspective, regarding themselves for hours in a mirror, in the effort to find in the physiognomy the reflection of the movements of the soul. They overlook the real appearance to come into contact with an unreal personality.

Among the adolescent there are those who commit suicide because of an exaggerated sense of honor, which they flatter themselves that they possess, often to merit, postmortem, the appreciation which they considered that they were entitled to during life. They believe that in committing suicide they are inflicting punishment on those who failed to appreciate their merits during life.

Other causes are found in two extremes of society, those who have been raised in poverty and have never seen the brighter side of life, and, at the other end of the scale, those who have had parents too rich or too cowardly to refuse anything, wherefore every thrill has been exhausted and there is only ennui left.

Japanese villages without medical facilities are to have them provided through the munificence of Mitsubishi, a famous millionaire, who has given 6,000,000 yen (\$2,340,000) for social welfare work. About \$600,000 will go for village medical service. Over 3,500 villages are without doctors and 1,000 are in "urgent need," according to the Japan correspondent of the *A. M. A. Journal*. A clinic or office will be built in each village at a cost of about \$600 and by 1936, 1,000 doctors will be appointed to these remote villages. As a rule, there will be no medical fee in case of poor farmers and fishermen, but for well-to-do people there will be a small fee, which is expected to be paid chiefly by the annual relief fund or from special grants made by the emperor yearly.

THE COMMON COLD

HAROLD S. DIEHL, M.A., M.D.

Minneapolis, Minnesota

The common cold, although rarely fatal, is the major cause of disability the country over and not infrequently leads to complications which cause serious and protracted illnesses. A survey made a few years ago by the New York State Department of Health showed that 57 per cent of the patients who sought medical service from physicians outside of the large cities did so because of colds or tonsillitis.¹ Few escape this affliction and the average incidence is about three attacks per person per year.²

Studies of the common cold,* although not yet productive of a specific method for its control, have taught us much concerning its etiology, epidemiology, prevention, and treatment. It is the purpose of this paper to present certain of the more practical conclusions which can be drawn from these studies. The common cold is not a specific disease entity, so various definitions of it might be given, but we will consider only acute conditions of the upper respiratory tract characterized by nasal discharge and congestion. Sore throat and fever may or may not be present.

ETIOLOGY

As the name cold suggests, this condition was long thought to be related to atmospheric conditions. More recently attention has been centered upon specific organisms which have been described as its cause. There is, however, abundant evidence to indicate that general factors as well as specific germs play a part in the production of colds. In fact, it is hardly reasonable to suppose that but one causative agent could be responsible for this symptom complex of the upper respiratory tract when it is common knowledge that various physical agents and organisms can produce pathological reactions in the lower respiratory, gastro intestinal, urinary, and genital tracts. The organisms and physical factors considered of greatest importance

in the production of the common cold follow.

A Filterable Virus Following the suggestive work of Kruse,³ Dochez and his colleagues⁴ in New York, and Doull and his colleagues⁵ in Baltimore demonstrated that a filterable virus is capable of producing in man and in chimpanzees symptoms and findings typical of an acute cold. This virus was obtained from human subjects with colds and so probably is the etiologic agent of certain outbreaks or epidemics.

Dochez⁵ describes the common symptoms of this "virus cold" in carefully isolated human subjects as "stiffness of the nose, sneezing, sore throat, and headache. No fever was observed during the course of the attack. The duration of the cold was approximately one week." Objective findings consisted of "injection of the conjunctivae, profuse nasal discharge, mucopurulent postnasal discharge, frank inflammation of the nasopharynx with swelling of the lymph follicles and continuous cough."

This benign course, however, occurs only when the subjects are carefully isolated, otherwise this acute process is usually followed by secondary infection with potential pathogens of the nose and throat. These secondary infections usually last two or three weeks and may involve the paranasal sinuses. Apparently either this virus activates organisms which are present in the nose and throat or the intense reaction of the nasal mucous membrane to the virus decreases local resistance to a point that organisms of low virulence are able to set up infections.

Bacterial Colds Various bacteria, but more particularly the micrococcus catarrhalis, the streptococcus, the influenza bacillus, and the pneumococcus are considered capable of producing acute infections of the upper respiratory tract.^{2, 6} A "marked sore throat" is a frequent early symptom of many of these bacterial infections, coryza following as the infection extends upward into the nasal passages. On the basis of a recent study of colds in the

* Thomson and Thomson recently published a review of more than 2,000 papers on the common cold.²

Virgin Islands Milam and Smillie¹⁰ feel that colds are caused by some specific agent with which we are not yet familiar.

Influenza, although considered primarily an infection of the lower respiratory tract, frequently presents symptoms of coryza. In fact, Doull and Bahlke¹¹ report that in an epidemic of influenza among the resident nurses of Johns Hopkins Hospital, 51 per cent of the cases exhibited coryza as "first day" symptoms.

The channel of most frequent spread of these communicable colds probably is through the respiratory tract, although Bliss and Long⁷ report several cases of acute colds in which the mode of transmission seems to have been by means of food. The rapidity with which the acute cold may spread through a community is illustrated by the observation of Heinbecker⁸ that practically 100 per cent of the natives in certain Eskimo villages developed acute respiratory infections with sneezing, coughing, and spitting, within 72 hours after the arrival of their party.

Allergic Colds. Allergic rhinitis is coming to be a well-recognized condition, but the frequency with which it occurs and the chronic reaction of the nasal mucous membranes which it produces, usually diagnosed as sinus disease, are not generally appreciated. In a series of 100 students (See Table I) who were referred to the Nose and Throat Department of the Students' Health Service of the University of Minnesota because of suspected sinus disease, 70 had slow sedimentation rates, suggestive of allergy, and 30 had normal or rapid rates. Sinus x-rays of the entire group showed cloudiness in 65 per cent of the cases with normal or rapid sedimentation rates, and in only 25 per cent of the group with slow rates (probably allergic). Antrum irrigations were then done on those patients whose x-rays

showed cloudiness. In the group with slow sedimentation rates (probably allergic) the irrigating fluid returned clear in 100 per cent of the cases; while pus was found in 85 per cent of the group with normal or rapid rates. Such conditions, although clearly allergic reactions of the nasal mucous membranes, are frequently thought to be ordinary colds and are treated as such.

In addition to the condition of definite allergic rhinitis certain things suggest an element of hypersensitivity in the common cold. For example, the nasal symptoms of hay fever and of acute coryza are practically identical; students who are subject to hay fever and asthma report more colds than students without these manifestations of allergy; and it is common knowledge that under similar conditions of exposure certain persons rarely have colds while others experience numerous colds each year. The usual explanation for this is that one group is immune and the other susceptible to colds. On the basis of our knowledge of immunity, however, the ones who report frequent colds should have the higher degree of immunity, not the ones who rarely have colds. A hypersusceptible group, on the other hand, would continue to have repeated colds rather than to develop an immunity to them.

Physical Factors. Exposure to drafts and chilling of the body frequently results in congestion of the nasal mucosa which may develop into a typical cold. The mechanism through which this disturbance of the mucous membrane occurs doubtless is the vasomotor system. Several investigators¹² have shown that chilling of the body surface produces a vaso-constriction of vessels supplying the nasal and pharyngeal mucous membranes, with an accompanying drop of several degrees in the temperature of the nasal mucosa. Why this is followed by nasal congestion, discharge, and frequently infection has not been explained.

Kerr and Lagen¹³ question the infectiousness of the common cold because they were unable to transmit colds to susceptible individuals either by exposure to patients with acute colds or by inoculation with the nasal secretions of individuals suffering with fresh colds, and are inclined to the hypothesis that "the excessive cooling power of the air at certain times, acting upon the body when the periphery is open

[illegible]

volved is probably one of desensitization, hence best results can be expected if the vaccines consist of organisms to which the patients are sensitive.

Ultraviolet Light. Several years ago ultraviolet light was widely advocated for the prevention of colds. The logic for this was that colds are most frequent during the season of the year when ultraviolet rays in the atmosphere are at a minimum. Most of the controlled studies, however, fail to show clear-cut benefits from its use.¹⁷ Smiley¹⁸ who has been studying colds at Cornell University reports that epidemics of colds are largely limited to "cold susceptible groups" and that the interest of at least one-seventh of these students can be aroused and sustained by offering "cold prevention" classes. In these classes matters of diet, ventilation, toning up of the skin vessels by ultraviolet rays are stressed, and in special cases use of vaccines and the correction of abnormalities of nose and throat advocated. Among students who follow the instructions given, Smiley says "that an average reduction of approximately 46 per cent in the incidence of colds can be prophesied. Which of these various factors is of most importance is a question, but the ultraviolet or sunlight bathing is undoubtedly an essential factor in arousing and sustaining the interest of the patient in the project."

Vitamins. The two vitamins most frequently advocated and advertised for the prevention of colds are vitamin A, as found in codliver oil, halibut liver oil and carotene, and vitamin D, as found in codliver oil and viosterol. The general subject of the relation of diet and vitamins to infection has been recently well reviewed by Clausen¹⁹ and by Robertson.²⁰

Vitamin A deficiency in animals unquestionably increases susceptibility to respiratory infections; but inasmuch as this vitamin is found in the average diet, is stable to heat, is stored by the body and is necessary in only minute amounts in order to prevent symptoms of deficiency, it clearly does not follow that the addition of this vitamin to the average diet will increase resistance to respiratory infections. In fact, studies of the carotinoid pigments of the blood by Clausen²¹ suggest that only 5 to 10 per cent of older children *might* possibly be benefited by the use of carotene. Clinical studies²² in which the diets of children and of college students were sup-

plemented by halibut liver oil and carotene, respectively, have failed to show that either of the substances is effective for the prevention of colds. There is, however, some suggestion that vitamin A may be a factor in the prevention of certain complications of colds, such as pneumonia, sinus infections, and otitis media.

Vitamin D is believed effective by many individuals for the prevention of colds but there have been no studies which show that the addition of this vitamin to the average diet increases resistance to infection.

Codliver oil, which contains both vitamin A and vitamin D, was reported by Hess, Bahrenberg, and Lewis²³ to have no influence upon the susceptibility of a group of infants to respiratory infections. Holmes, Pigott, Sawyer, and Comstock,²⁴ on the other hand, found a lower incidence of colds and less loss of time among a group of industrial workers whose diets were supplemented by a tablespoonful of codliver oil per day than among a control group who received no codliver oil. These results have encouraged Dr. Sawyer and his associates to continue their studies, the early results of which look very encouraging. The final reports of these studies will be awaited with interest.

Vitamins B, C, and E are sometimes said to be related to infection because animals on diets without these vitamins are susceptible to infections and frequently succumb to them. Such animals, however, are always in a greatly weakened condition; hence, this observation cannot be accepted as evidence that the injection of extra quantities of these vitamins will prevent infections.

If one were to summarize the present status of our knowledge concerning the value of vitamins in the prevention of respiratory infections, he could only conclude that convincing evidence is not yet available to prove that the addition of any of the vitamins to the average diet increases resistance to colds, but that some of the more recent studies are sufficiently suggestive to make further investigation in this field much to be desired.

Other measures at times suggested for the prevention of colds, such as alkalization and the use of oils or antiseptics in the nose, are supported by no scientific evidence to indicate that they are of any value whatsoever.

TREATMENT

The methods commonly utilized for the treatment of colds can be divided into two groups—general and medicinal. Of these the more commonly utilized are as follows:

Exercise, although rarely recommended by physicians, is a form of treatment extensively used and believed in by many people. They describe it as "sweating out a cold" but what they actually experience is the relief of nasal congestion and discharge which accompanies the peripheral dilatation produced by the exercise. As to whether this relief of congestion has any lasting benefit on the course of the cold no accurate information is available. The apparent benefit which certain patients obtain from massage is probably the result of the same mechanism.

Hot baths and certain types of physiotherapy also cause peripheral dilatation and concurrent relief of nasal congestion. If hot baths are followed by bed rest with sufficient covers to prevent cooling the effect is prolonged and the end result probably better.

Bed rest is considered by many physicians as the best treatment for the common cold but no actual studies have been made to determine how important it really is in the minor infections.

Catharsis has long been used for the treatment of colds on the theory that it aids in the elimination of toxins. MacDonald²⁵ questions its value, but his results are based on a very small series of cases.

Fluids in large quantities have long been considered a valuable adjunct in the treatment of colds, presumably on the theory that with the greater intake of fluids the elimination of toxins is increased. The value of this practice, however, is based upon presumption rather than scientific evidence. In fact recent observations made by members of the Department of Pediatrics of the University of Minnesota,²⁶ suggest that epileptic children on ketogenic diets with restricted fluid intake resist infections better than when their diets and fluid intakes are unrestricted. Some preliminary experiments on animals seem to confirm this observation. Additional studies on this point are at present in progress.

Drugs in the treatment of colds have been a subject of special study for the past several years in our Students' Health Service of the University of Minnesota. In

these studies²⁷⁻²⁹ every possible effort was made to so control them that the personal element would be entirely eliminated in the determination of results. In brief, the procedure followed to accomplish this was as follows:

Students with colds reported to physicians who made whatever examinations were indicated, recorded symptoms and findings, and wrote prescriptions for "cold medication." These prescriptions were then filled by a pharmacist who used in sequence the medications being studied at that time. Four days later cards reporting the subsequent courses of their colds were submitted by the patients and the results of the treatment rated by two physicians, neither of whom had any knowledge as to what medication had been taken by the patient. The ratings used to indicate results were "definite improvement or complete relief, questionable improvement, and no improvement" within 24 to 48 hours after first taking the medication. In final analysis, however, only reports of "definite improvement or complete relief" were considered significant. Finally the pharmacist's record was obtained and the results were classified according to the type of cold and the medication which had been used.

For purposes of classification the colds were divided into acute coryza, subacute colds, influenza, pharyngitis, and other respiratory infections. Most of the cases, however, had acute coryza, which was defined as a cold of not more than four days' duration with serous discharge from the nose and with or without sorethroat, headache, fever, or other symptoms, or subacute colds, which were defined as colds with serous discharge of more than four days' duration or with a mucopurulent discharge of any duration.

Among the medications administered were included some tablets and capsules containing only milk sugar. These were used for control purposes to determine what proportion of the patients would recover spontaneously within the period covered by the report. The results reported by the patients who received these control tablets indicate that 35.5 ± 3.0 per cent of patients with acute coryza experienced definite improvement or complete relief within 24 to 48 hours after reporting for treatment. This high percentage of spontaneous recovery must be kept in mind

when considering the results obtained with other medications.

The various medications studied and the results obtained with them are shown in Table III. The more significant of these results may be briefly summarized as follows:

Dover's Powder. This mixture of opium and ipecac, which originally included also potassium chlorate, was suggested by Thomas Dover in the latter part of the seventeenth century for the treatment of gout. Later it was advocated as a sweating powder in the treatment of colds and for many years was extensively used for this purpose. Our results indicate that this preparation has merit in acute coryza, but that the same amount of opium is just as effective without the ipecac.

Morphine, with which for reasons stated in a previous paper²⁷ this study was started, and its derivative, dilaudid (dihydromorphinone hydrochloride) are effective in relieving nasal discharge and congestion in a large percentage of patients. However, toxic symptoms which follow the use of both morphine and dilaudid and the addictive possibilities of morphine make these drugs undesirable for the treatment of colds.

Codeine-Papaverine. Codeine alone and papaverine alone are each of definite value, although of less value than morphine, in

TABLE III.—RESULTS OF TREATMENT OF ACUTE CORYZA

Medication ¹	Cases	Percentage reporting definite improvement	Toxic symptoms
Codeine-papaverine.....	1515	71.8 ± 0.8	4.9

the treatment of coryza. Together, however, codeine and papaverine are just as effective as morphine, are followed by a distinctly lower incidence of untoward symptoms, such as dizziness, headache, nausea, vomiting, and so on, and are practically without addictive possibilities. Reports from more than 1,500 students who have used the codeine-papaverine combination in acute coryza* indicate that 72 per cent felt that they obtained "definite improvement" or "complete relief" as a result of its use.

Certain other studies which were made of the codeine-papaverine combination indicate that: (1) The proportions of choice are ¼ grain codeine with ¼ grain of papaverine; (2) this mixture of codeine and papaverine gives a significantly higher percentage of good results and produces less headache, dizziness, nausea and vomiting than a corresponding quantity of codeine alone or papaverine alone: in other words, codeine and papaverine in this dosage apparently act synergistically; (3) the optimum dosage of this mixture for an adult of average size is one tablet or capsule after each meal and two at bedtime; if the cold is well-established this dosage should be continued for 2 or 3 days; (4) the effect observed by persons who report improvement is a prompt decrease or complete disappearance of nasal discharge and congestion; (5) the earlier treatment is instituted the higher the percentage of good results reported—in fact, if this preparation is utilized at the very onset of symptoms a few tablets or capsules are usually sufficient to prevent further progress of the cold; when treatment is delayed from the first to the fourth day the proportion of beneficial results reported declines from 73.3 per cent to 60.4 per cent; (6) students who used this preparation for the treatment of coryza lost significantly less time from school than did those who used other medications.

The mechanism through which opium and its various derivatives act to check coryza is not entirely clear, but certain observations suggest that action may be primarily through the vasomotor system.²⁸

The results obtained with other drugs utilized for the treatment of colds include the following:

* The exact preparation used in the study was Co-pav-in" (codeine sulphate, ¼ grain, with papaverine hydrochloride, ¼ grain) which is prepared by the Eli Lilly Company under license from the University of Minnesota.

Quinine sulphate was followed by a significantly higher proportion of good results than were reported for the control tablets, but was less effective than most of the opium derivatives.

Atropine sulphate in many cases produced temporary dryness of the nose and mouth but had no apparent effect upon the course of the cold.

Acetyl salicylic acid; a combination of acetylsalicylic acid-acetphenetidin-caffeine; ephedrine sulphate; halibut liver oil; sodium bicarbonate; and a calcium-iodine preparation gave results slightly, but hardly significantly better than the control tablets.

Ephedrine sulphate, 1 per cent, used locally in the nose produced temporary relief of nasal congestion but seemed to have no effect upon the progress of the cold. The same strength of ephedrine sulphate in 1-5,000 merthiolate solution was followed by a somewhat higher proportion of good results, but was less effective than the opium derivatives.

A preparation which is nationally advertised and extensively used for the "internal treatment" of colds gave about the same proportion of good results as did soda, and acetylsalicylic acid; and a nationally advertised medicated oil to drop into the nose, although used by millions of people, gave no better results in this controlled study than did the sugar tablets.

In sub-acute and chronic colds the codeine-papaverine combination usually relieved nasal congestion and seemed to be of benefit in approximately half of the patients. The difference, however, between these results and those reported for other medications is hardly great enough to be of significance.

SUMMARY

1. Various actual and contributory causes play a part in the production of what we call the common cold. Chief among these are a filterable virus, various bacteria, a hypersensitive state, poor ventilation, and exposure to drafts. The intense reaction of the nasal mucosa, which occurs in the initial stages of the common cold, seems to predispose to infection by potential pathogens which may be present in the nose and throat.

2. No specific measure has yet been shown to be of sufficient value for the prevention of colds to justify its indiscriminate use. Further studies of vitamins and vaccines, however, are highly desirable. In certain individual cases of chronic colds autogenous vaccines or carefully selected stock vaccines seem beneficial. General measures carefully carried out have been found effective in reducing the incidence of colds among "cold susceptible" groups.

3. A controlled study of various drugs used for the treatment of colds indicates that the highest percentage, 72 per cent of 1,515 cases, of good results with least unpleasant symptoms followed the use of a combination of codeine and papaverine. This preparation, as well as certain other opium derivatives, is followed by prompt diminution or complete relief of nasal discharge and congestion. This relief of symptoms not only makes the patients more comfortable but seems also to decrease the probability of secondary infections. Of the other medications studied certain ones seemed to have some merit, but none was nearly so effective as these opium derivatives.

CANCER QUACK DIES OF CANCER!

Charles W. Mixer, self-styled cancer specialist of Hastings, Mich., is dead of cancer on the eve of his prosecution on charges of violating the Federal Food and Drugs Act. His principal medicine, "Mixer's Cancer and Scrofula Syrup," composed of potassium iodide, senna, licorice, yellow dock root, sarsaparilla, wintergreen, glycerine, alcohol, and sugar syrup, had for a long time evaded the Federal law, until Food and Drug Inspectors intercepted a shipment to Chicago and based the recent case on it, says a report from Washington. This step was necessary, as the Federal government can bring cases under the Food and Drugs Act against interstate shipments only.

Even during Mixer's last illness, his office force continued to sell and ship the so-called "cancer cure," which fact led the Government to request that the trial proceed without delay, in spite of the defense attorney's plea that the defendant was seriously ill and could not stand trial.

Mixer's death has now blocked the suit, which will necessarily be dismissed automatically. He employed a physician to care for his own cancer. By correspondence he "diagnosed" his unseen patients, frequently without even a statement from them of their condition or symptoms, and, when they finally ordered some of his preparations, he sent them something else selling for slightly less, carefully explaining that his experience had shown it would be better to take this other medicine until the system became accustomed to the treatment. This procedure left a so-called "credit" which was not enough for additional treatment, but which Mixer used as an inducement to the patient to purchase

more on the payment of a little more money. In this manner, he dealt mostly with poverty-stricken people unable to afford hospital care or a doctor's attention.

In his lengthy correspondence with each patient, there usually occurred periods when the spirits of the patient rose above the gloom and discouragement ordinarily filling the letters, and Mixer used these cheerful and optimistic letters as testimonials of the worth of his "remedies," carefully suppressing the others.

BABIES HUSKIER NOW

Babies born in New York State today have a far better chance of surviving the first year of life than did those born twenty-five years ago, according to the 1933 annual report of the Division of Vital Statistics.

Infant mortality in the State has been declining not only in terms of the number of births but also in relation to all deaths. Twenty-five years ago, out of one hundred deaths of all ages, 19 were of infants under one year of age; in 1933 the proportion dropped to seven. In other words, the rate of infant deaths has declined considerably faster than the general death rate.

Travelers will be interested to know that the sources of drinking and culinary water used on interstate railroads, buses, vessels, and airplanes are inspected and certified by the United States Public Health Service. Ninety-four per cent of these supplies were inspected and certified during the year. It was found necessary to prohibit the use of 28 of these supplies.

RUPTURE OF SUPPURATIVE CERVICAL ADENITIS INTO THE MIDDLE EAR

M. BERNARD BRAHDY, M.D. and LOUIS H. SCHWARTZ, M.D.

Mount Vernon

From the Department of Pediatrics, Cornell University Medical College, New York City

Practically all cases of nontuberculous suppurative cervical adenitis either heal spontaneously or require incision and drainage. It is unusual for an abscess of the cervical lymph nodes to rupture into the external auditory canal or the middle ear. The only reports of such cases we have found in the literature were published by Campbell¹ in 1930 and by Rosenwasser² a few months ago. One of Rosenwasser's 4 cases occurred 18 years ago. In an active otologic practice during the last 25 years one of us (L. H. S.) saw a child with a cervical adenitis which ruptured into the external auditory canal. The condition no doubt occurs more often than indicated by the preceding few references. The paucity of literature on the subject may be due in part to the lack of recognition that an abscess in the upper cervical region can drain through the ear. Brief consideration of the pertinent anatomic structures involved will make such a possibility clearer.

ANATOMY

Bones. According to Cunningham³ "the occurrence of a deficiency in the floor of the external auditory canal is not uncommon in the adult. It is met with commonly in the child till about the age of five and is due to incomplete ossification of the tympanic plate." We examined numerous skulls of children and adults and were surprised to find how often the suture of Santorini in the floor of the external auditory canal was patent, due to lack of fusion of the temporal ring and the squamous portion of the temporal bone. A probe passed through the patent suture entered into either the external canal or the middle ear depending upon how the probe was directed and the location of the patency in the suture line.

In addition, there may be an actual defect in the bone itself. According to Barnhill and Wales⁴ "a small dehiscence is found in the anterior wall [of the auditory canal] commonly up to the sixth year of life. Sometimes through the lack of development the dehiscence persists and becomes a

possible pus channel for infection from the auditory canal to the articulation of the jaw." Later they state that "the anterior wall is behind the condyle of the lower jaw and is found in relation to the parotid gland. This wall may be paper-thin or, through lack of development, it may be perforated."

Campbell¹ discusses a third possible route for the passage of pus upward into the auditory canal. He states that "in young children up to the age of four years the attachment of the membranous to the bony portion is very loose. There is loose fibrous connective tissue, which as the patient grows older, becomes firm and tense and which unites more densely the cartilaginous and bony portions. It is for this reason that perforations through this junction of the cartilaginous and bony portions of the wall are seen more frequently in children than in adults."

Lymph Nodes. The lymph nodes which are anatomically related to the floor of the auditory canal are the subparotid and upper deep cervical nodes. The subparotid nodes are beneath the parotid salivary gland, between it and the pharyngeal wall in the lateropharyngeal space. They are superficial nodes which drain the nasal fossa, nasopharynx, and eustachian tubes.⁵ The superficial cervical lymph nodes drain into the chain of deep cervical nodes which, Campbell feels, are probably most concerned in the production of abscesses that drain into the external auditory canal. The deep cervical chain extends from just beneath the ear downward under the sternocleidomastoid muscle.

CASE REPORT

The subject of the following report is the son of a physician. His family history and past history have no bearing upon the condition under consideration.

H. G., aged 7 years, had an acute pharyngitis on December 9, 1933 from which he recovered in a few days. At that time he had a palpable submaxillary lymph node on the right side. On December 22 he developed a more severe throat infection with patches of exudate on both tonsils.

The submaxillary nodes were tender. Two days later the exudate on the tonsils had disappeared, but there was an enlargement of the right upper cervical lymph nodes. These continued to increase in size until there was a large, acutely tender, reddened swelling around the angle of the mandible on the right side. Opening the mouth caused considerable pain. The temperature fluctuated three or four degrees Fahrenheit daily. Slight peripheral injection of the right ear drum was noted on January 1. On January 5 there was a little softening of the inflammatory mass in the neck. The same day and also the following day the patient complained of pain in the right ear. The drum showed a more intense marginal injection than previously, but there was no bulging and Shrapnell's membrane was practically normal. There was no tenderness on direct pressure over the mastoid, nor was there any sagging of the posterosuperior part of the canal wall. The floor of the external auditory canal was tender and later became reddened. During the following days the floor of the canal bulged upward more and more until the lumen was almost occluded. Dr. Jerome Ziegler saw the patient in surgical consultation and advised that incision of the softened mass in the neck be delayed for a few days. On January 9 there was a slight sero-sanguineous discharge from the right ear and in the course of two days this became more profuse, thicker and purulent. Culture of the pus by Dr. J. E. Blair revealed *Streptococcus hemolyticus*.

At this time the swelling in the neck was very large, extending from the tip of the mastoid to an inch below the angle of the jaw. The mass was red, soft, and exquisitely tender. Slight pressure on the inflammatory mass increased the discharge of pus from the external auditory canal. Profuse drainage continued for a week during which time the swelling in the neck decreased in size. The peak reached by the daily rise in temperature became lower. After the first week the discharge became thinner and less profuse. The floor of the auditory canal gradually receded and when the entire drum could be visualized again one could see a perforation in the lower quadrant through which pus drained. To further establish the relation between the cervical abscess and aural discharge the following was done: The canal was carefully dried and the perforation in the drum was observed while gentle pressure was exerted over the swollen glands in the neck. As soon as pressure was applied to the glands, pus discharged through the opening in the drum and rapidly filled the auditory canal. Slight drainage continued for another two weeks and the perforation in the drum closed shortly after the discharge stopped. When the swelling in the neck subsided, a firm, slightly tender mass about an inch long was palpable at the angle of the mandible. The convalescence was uneventful.

COMMENT

Our patient had a suppuration of the upper deep and superficial cervical lymph nodes, some of which are in relation to the floor of the external auditory canal. Since the floor of the canal was pushed upward but the actual rupture of the pus occurred into the middle ear, the probability is that

the suture of Santorini in the floor of the bony canal was patent. That the pus did not rupture directly into the canal may have been due to the more resistant fibrous tissue at that site in comparison to the tissue lining the middle ear. The appearance of the drum of our patient and the absence of signs of mastoiditis ruled out an acute purulent otitis media. The pus which accumulated in the middle ear perforated through the lower quadrant of the drum and drained out of the external canal. Pressure on the glandular mass in the neck caused pus to well up into the auditory canal. The drainage was profuse until the glandular swelling had decreased considerably and then the discharge gradually subsided.

In each of the five cases reported in the literature pus from the suppurating cervical lymph nodes ruptured into the external auditory canal. In one of Rosenwasser's patients there was a perforation in the drum, but there was a complicating mastoiditis, indicating that there was an acute otitis media present at some time. In our case no suppuration of the middle ear was present and there was no perforation in the floor of the external auditory canal. The cervical abscess ruptured into the middle ear and there followed a spontaneous perforation of the drum with discharge of pus. The abscess drained completely through the middle ear.

Drainage of a cervical abscess through the ear is not only of anatomic interest but also of clinical significance. When a patient has a high cervical abscess requiring surgical treatment and the floor of the auditory canal is pushed upward, an external incision may be obviated. Instead, an incision into the floor of the canal at the point of bulging is likely to drain the cervical abscess. This may be a more desirable site for incision, especially in girls, to avoid disfiguring scars on the neck. However, if drainage is not adequate after an intra-aural incision, the usual external incision can be made later.

The early otologic manifestations in uncomplicated cases are of especial interest. There is an acute otalgia, the floor of the canal is red and pushed upward, and the drum may or may not be injected. However, there is no bulging of the drum, nor are there signs of mastoiditis. Since there is no acute purulent otitis media, myringotomy is not indicated. In excluding mastoid tenderness in these cases, particu-

Early when there is some involvement of the drum, persistent pain referable to the ear, forward protrusion of the lobe of the ear, and swelling over the mastoid, one must be careful to exert pressure on the bone itself and not on the inflamed soft parts. However, the presence of a red, bulging drum, mastoid tenderness, and possibly sagging of the posterior superior part of the canal wall indicates a complicating or coincident mastoiditis or otitis media requiring additional treatment. A roentgenogram may show the destruction of mastoid cells.

SUMMARY

Rupture of an abscess of the cervical lymph nodes into the external auditory canal or middle ear is unusual. Pus can pass into the auditory canal by three routes: (a) through the fissure of Santorini, (b)

through the fibrous tissue between the cartilaginous and bony wall of the external canal, and (c) through a dehiscence in the bony wall of the canal. The only way pus can pass into the middle ear is through the fissure of Santorini. The upper deep and superficial (subparotid) cervical lymph nodes are in relation to the floor of the middle ear and external canal. The case reported had an acute suppurative adenitis of the upper cervical lymph nodes following an infection of the throat. A large cervical abscess formed. The pus passed upward lifting the floor of the external auditory canal and rupturing into the middle ear. The drum perforated and pus discharged through the external canal. The patient made an uneventful recovery. This is the first reported case of drainage of a cervical abscess through the middle ear.

THE USE OF CECAL DRAINAGE IN RUPTURED APPENDICITIS

GEORGE M. DORRANCE, M.D. and STEPHEN W. NEALON, JR., M.D.

Philadelphia, Pennsylvania

Many a surgeon has observed and not a few have commented in their writings that the occurrence of a spontaneous fecal fistula during a stormy postoperative convalescence in cases of perforated or ruptured appendicitis in which drainage was used resulted in an almost immediate cessation of the alarming symptoms.

Eight years ago, the senior author decided to drain the cecum at the time of the operation in an acute ruptured appendicitis so as to obtain the benefit at once.

The youngest patient on whom it has been used was 18 months and the oldest 67 years. In all, the method has been used in about 30 cases.

The applied physiology is considered to lie in that the condition causes decompression of the intestine allowing the gas to escape, thus preventing distension. Three advantages are enumerated:

(1) The Murphy drip is given at regular intervals through the cecal opening, thus placing it in that portion of the intestine where water is best absorbed, permitting an accurate record of the amount the patient has absorbed.

(2) The nursing problem is simplified as the Murphy drip is a real problem in children. The bed does not become wet nor is the patient disturbed as in cases where we use the rectum.

(3) Frequently liquid fecal material passes out through the drainage tube and if necessary an enema may be given through the catheter.

Observations are that fewer desperate postoperative crises occur, in this series there was no mortality.

At first this drainage method was used only occasionally and then in cases that

were really desperate, many of which subsequently became ordinary cases. At present the authors incline to use it in all ruptured cases where drainage is indicated.

The fecal fistulas have all closed within three or four weeks; to date there has been no permanent fistula.

While its performance at the time of primary operation is advised, if a patient becomes desperate with toxic distension, there are no obvious contraindications to producing a fecal fistula at any time post-operatively. This secondary fistula may show more complications than a primary one. The authors have not had a sufficient number of cases to judge the advantages and disadvantages of this procedure.

METHOD

The method of performing primary cecal drainage is to remove the appendix, ligate the meso-appendix, and then apply a purse-string suture around the stump. A 20 French soft rubber catheter is introduced through the opening into the appendix stump for a distance of about 3 inches and the pursestring suture tightened and tied.

As a precaution a plain No. 1 catgut suture is passed through the gut, catheter and gut and ligated. This prevents the catheter from coming out too soon. The cecum is replaced in the right iliac fossa, a clamp is placed on the distal end of the catheter, and two drains of gauze surrounded by rubber dam (Penrose drains) are placed down to the cecum. The peritoneum is sutured around the catheter and drains. The fascia and skin are sutured

in the usual manner to prevent the intestine from protruding.

Gas coming from the catheter if the clamp is removed, is often noted even when the patient is still in the operating room. The patient is returned to bed and placed in the usual Fowler position and the Murphy drip is started within two hours.

The reason for using a catheter, with or without cutting off the tip, is that by virtue of the thickness and texture of its walls kinking is prevented. The catheter is left in place until it comes away of its own accord. This may occur before or after the drains are removed; on the average both are out between the seventh and the ninth day.

For this paper the last one hundred cases of appendicitis on the authors' service were analyzed.

Acute	68
Subacute	13
Subacute abscess	7
Chronic	12
Total	100

The type of drainage used:

Primary cecal drainage.....	7
Secondary cecal drainage.....	1
Penrose drain	14
No drain	78
	100
Deaths	0

The conclusion is that the use of the Fowler position, the Murphy drip, and cecal drainage in ruptured cases reduces the mortality and morbidity of appendicitis.

2101 SPRUCE STREET

PERHAPS THE DOCTORS HELPED, TOO!

There is yet no evidence that the depressed economic conditions of the past few years have lowered the general health of the people of the United States, according to the Surgeon General of the United States Public Health Service. This information is presented in his annual health accounting to Congress which reports the activities of his organization for the 136th year of its existence.

While death rates are available from year to year as an index to health, the Surgeon General has not relied upon these rates alone but has instituted special studies of actual sickness over a period of several years, be-

ginning in 1929, in 10 localities where the depression has been most severe. These studies show higher sickness rates in the economic group rated in comfortable circumstances in 1929 but subsequently reduced to the lower economic class.

The most important reasons given for the continuation of general good health are the vast work of the relief agencies and the fortunate absence of wide-spread epidemics.

It is interesting to note that for the calendar year 1933 the general death rate, 10.5 per 1,000 population, was the lowest ever recorded in the United States; and the rate for 1932 was next lowest, 10.8 per 1,000.

CLASSIFICATION OF MENTAL DISORDERS

ROSS E. HEROLD, M.D.

Clinical Director, Willard State Hospital

Mental disorders can be classified under two main headings: (a) The organic group, or those occurring on a physical basis, and (b) the functional or psychogenic group.

In this discussion the author does not propose to say a great deal about the organic group beyond mentioning some of the most important subgroups. He would also like to emphasize at this point that the mental system is as much a body system as the cardiovascular, muscular, gastrointestinal systems, etc., and in dealing with any individual, a physician must bear this point in mind, in order to properly treat any illness, of which the patient might complain. Every case of physical illness shows some mental aspects which, of course, may be very mild. It is only in those patients that show predominating mental abnormalities, in connection with their physical illness, that hospitalization in a mental hospital becomes necessary.

Various infections frequently result in more or less prolonged mental derangement requiring hospital care. Acute physical diseases, such as pneumonia, are usually accompanied by delirious episodes which, however, subside as the physical disease improves, and only a very small percentage of these individuals require care in a mental hospital.

Chronic infections, such as syphilis, produce many cases of mental disorder, and about 10 per cent of admissions to State hospitals are due to this disease.

Intoxications due to alcohol, drugs, and other external toxic agents, are responsible for their quota of admissions to mental hospitals, and various traumatic conditions, such as skull fractures, result in quite a number of admissions. Arteriosclerosis is a responsible factor in many cases, as are other less common physical disorders.

In all cases of organic mental disease, treatment of the underlying physical disorder is the only possible way of effecting any improvement in the condition. Many of the disorders do not respond to any known methods of treatment.

During the last few years, the most marked increase in admissions of patients

suffering from organic mental disease, has been in three groups, *viz.*, general paresis, arteriosclerosis, and alcoholism. We know of no way to prevent or cure arteriosclerosis; we cannot control the drinking habits of a community as this is almost purely a social problem, but much preventive work can be done in the prevention of general paralysis. Many of the patients suffering from this disorder give, on admission to the hospital, a history of having had no treatment or only very little treatment during the early stages of their syphilitic infection. If all cases of syphilis were treated early and intensively, the number of admissions due to general paralysis could be materially reduced.

Once definite signs of general paralysis have developed, the most we can hope to do in a mental hospital is to arrest the progress of the disease by various forms of fever therapy, such as malaria, accompanied by intravenous use of the various arsenical preparations. The usual length of life was about two to three years previous to 1924, but we have several patients who were treated in 1924 and who are still alive, some able to support themselves.

Now, to discuss for a few moments the so-called functional psychoses, or those of psychogenic origin. Much discussion has been offered during the past few years regarding the use of term psychogenic. Many authors claim that no mental disorder can occur without definite physical changes, even though we have not advanced to the point, in medical science, where these physical changes can be demonstrated grossly or microscopically. The majority feel, however, that a great many cases can be explained on a purely psychogenic basis.

The author does not propose to describe in detail each separate psychosis or disorder of a psychogenic nature, but will endeavor to show by several concrete examples how such conditions may arise. All obstetricians have seen mental aberrations accompanying pregnancy and varying in their degree of severity. Various environmental factors may have a definite bearing on these mental states. A pregnancy may occur in a family where there

is no financial backing to add another child. This may result in worry on the part of the prospective mother and may result in a definite psychosis. Again, under similar conditions the pregnant woman may feel that she is not capable of assuming the added responsibility for the care of the child. Anyone of many similar factors may result in a psychosis and if the underlying mental state is not recognized early, and the proper frame of mind established, the aberration may be so marked toward the end of the pregnancy, or shortly afterwards, that hospitalization may become necessary.

All school physicians have seen children who, apparently, are not progressing as well as they should. The teacher may request that they be sent to the child guidance clinic with request for an intelligence rating. Complete physical examination may reveal defective eyesight or hearing and when this is corrected, improvement may be noticed in the child's progress. If these factors are not recognized and treated, the child may continue to lose interest in his work, may develop conduct disorders, or even delinquency, and we have an ideal background for the development of dementia praecox or manic-depressive insanity, depending on the personality and tendencies of the individual.

These two forms of functional mental disorders (dementia praecox and manic-depressive insanity) account for by far the largest number of admissions to State hospitals. The author has endeavored to show how such conditions may arise and will now try to describe as briefly as possible the essential features of each group when the disorder has become well established.

DEMENTIA PRAECOX.—The following features are sufficiently well established to be considered the most characteristic of this type of reaction.

(1) A seclusive type of personality or one showing other evidences of abnormality, in the development of the instincts and feelings.

(2) The appearance of defects of interest, and discrepancies between thought, on one hand, and the behavior and emotional reaction, on the other.

(3) A gradual blunting of the emotions, and often hypochondriacal complaints, suspicions, or ideas of reference; indifference or silliness with serious defects of judgment.

(4) Development of peculiar mental trends, often fantastic ideas, with odd, impulsive, or negativistic conduct, not accounted for by an acute emotional disturbance or impairment of the sensorium.

According to the prominence of certain symptoms in the individual cases, there are four main types of dementia praecox, but in many instances the symptoms are so numerous, that it is difficult to place an individual definitely, in one group.

(a) *Paranoid type* with prominence of delusions, either of a grandiose or of a persecutory nature, and often accompanied by hallucinations of the special senses. The delusions often result in antisocial or definitely criminal acts.

(b) *Catatonic type* in which there is a prominence of negativistic reactions, peculiarities in behavior, and often states of stupor or marked impulsive assaultive excitement.

(c) *Hebephrenic type* showing silly behavior with many peculiar mannerisms. These individuals often express delusions but do not react to them as does the paranoid type.

(d) *Simple type* showing defects of interest, or indifference, gradually developing into a state of apathy. In all types there is a gradual withdrawal of interest from their environment, in the end state of which there is no apparent connection between the individual's environment and his behavior.

MANIC-DEPRESSIVE DISORDERS.—This is the next largest group of functional psychoses. The manic-depressive disorders are fundamentally marked by emotional oscillations and tendency to recurrence. There are two main types.

(1) The *manic* reaction with pronounced feelings of well-being or irascibility, flight of ideas, overactivity, and distractibility. In the more pronounced phases of this type of reaction, the individual may be quite destructive and show assaultive tendencies.

(2) The *depressive* reaction with feelings of mental and physical insufficiency; despondent, sad, or hopeless moods, and in severe cases, marked retardation, often extending to the point of a stuporous reaction. The feelings of despondency and anxiety may be so pronounced as to result in suicidal attempts.

No attempt has been made in the discussion, to give a detailed description of all the forms of mental diseases.

For Better or Worse?

Governor Lehman's keen interest in the Workmen's Compensation Law is reflected in the speed with which three amending bills of prime importance have been introduced in both Senate and Assembly. Unfortunately haste has not been matched with wisdom in every case; and it is to be hoped that the Legislature will carefully consider the implications of each bill before taking action.

The O'Brien-Canney Act, which requires all compensation insurance not underwritten by self-insurers to be placed with the State Fund, seems innocuous on the surface. The medical profession of the State, however, has found the State Fund as ruthless and unfair in its dealings with physicians as any of the private carriers—indeed even more unfair. Unless the profession receives some definite assurance that abuses complained of will be promptly and surely terminated it cannot acquiesce in the virtual monopoly that the O'Brien-Canney bill would create. Any amendment of such far-reaching consequence should definitely provide that the injured worker may select his own doctor

from a list approved by the Medical Society of the State of New York or its component county units.

The second Act, sponsored by Senator O'Brien and Assemblyman Kantowski, is commendable in both purpose and form. Seeking to eradicate medical abuses such as fee-splitting and solicitation, it adds five physicians to the Industrial Council, thus giving medicine equal representation with Labor and Industry. Such an arrangement should materially help to prevent administrative controversies and procure wise solutions of the problems that continually arise.

The Coughlin-McCaffrey Act which extends the compensation laws to include all disabling diseases occurring in the course of employment has nothing but good intentions to commend it. In the absence of an accepted definition of "occupational" diseases, it would foster extensive malingering and force every doctor to become a detective. It would be far wiser first to formulate an acceptable definition of occupational ailments and then provide suitable compensation for them than to open the way to protracted controversies by extending the scope of the law in such a haphazard and indeterminate manner.

There is no doubt that the medical aspects of the Workmen's Compensation Act are gravely in need of reform; but there can be no satisfactory revision that does not encompass the medical point of view. Governor Lehman tacitly endorsed this principle last year by appointing a committee of ten physicians to study the situation. The profession will be keenly disappointed if he fails to translate the recommendation of his Medical Advisory Committee into law and throw his support behind opposite legislation.

Fluid Extract of Ergot

Despite the multiplicity of available proprietary concoctions of ergot, the U.S.P alcoholic fluid extract is still the most widely used preparation in obstetrical practice. The official extract of the National Formulary is an aqueous extract and of distinctly inferior therapeutic

efficiency. Pharmacologists and clinicians alike have been justified in suspecting that the biological potency of the alcoholic extract has diminished during recent years, and that either the active alkaloids are deficient in quantity, or the products of decomposition (amines) are present in excessive amount, or both. Such imperfections in the finished product may be due to chemical changes in the ergot before use, or in faulty manufacturing processes, and have unfortunately been responsible for controversial discussion.

There is no fundamental difference between Russian and Spanish ergot in their natural state, but variations in the method of curing, preserving, storing, packing, and shipping have resulted in noticeable changes in some of the ergot when received in the United States. Although sub-standard drugs may be imported and sold in this country, provided their actual quality is stated on the label, strict regulation of their final disposition is bound to be uncertain, and the wisdom of imposing so great a supervisory responsibility upon official inspection is open to serious question. Dampness, heat, mould, insect infection, and so on, are all inimical to the purity and strength of the crude drug.

"Reconditioned" ergot has probably been the basis of much of the dissatisfaction following the clinical exhibition of the fluid extract, because of the intrinsic deterioration incidental to decomposition or putrefaction. Both Thompson and Rusby examined a large number of samples of the fluid extract of ergot, and reached the conclusion that the cockscomb test is no criterion of the drug's purity or the preparation's biological activity. It behooves obstetricians to insist that the ergot used in the manufacture of the fluid extract be of prime quality, free from mould, slime, objectionable odor, insects, and discoloration, and that all the requirements specified by the United States Pharmacopoeia be rigidly followed; otherwise, the medical profession may have to limit the prescribing of one of the most useful remedial agents in its obstetrical armamentarium.

Liver Function Tests

During late years improvement in biochemical technic with consequent advance in our knowledge of chemical physiology has been of great practical value in the study of the physiology and pathology of the parenchymatous organs which are the main chemical laboratories of the body. The tests for renal function are a peculiarly elegant example. The kidney is preponderantly an excretory organ. Both the initial product, the blood, and the excretory product, the urine, are readily and conveniently obtained for analysis.

The functional study of the liver presents a much more difficult problem. The formation and excretion of bile may be, and probably is, an entirely separate and distinct process; but there are a host of physiological processes that have been rightly or wrongly ascribed to the liver that may or may not be confined to that organ. As each physiological function has been described in the experimental laboratory, no long period elapsed before a clinical test based on disturbance of this particular function was proposed.

The pitfalls have been many because of the enormous factor of safety provided by the liver. Mann and his associates have shown that the liver may be destroyed to a last minimal 20 per cent and this "saving remnant," even though severely damaged by the operation, can yet preserve normal function. Thus all the tests based on excretions of foreign sugars, destruction of injected amino acids, disturbances of cholesterol metabolism, do not indicate incipient cases of liver dysfunction with any reasonable certainty. However, the field of enzyme chemistry offers hope for a really sensitive indicator.

Somogyi¹ of St. Louis has developed a method of accurately determining the actual amount of starch-splitting enzyme in the blood, by the use of only 1 c.c. of plasma. He and his associates have found markedly low diastase values in icteric blood, in the blood in toxemia of pregnancy, and regularly in connection with

¹ Somogyi, M.: Blood Diastase as an Indicator of Liver Function, *Proc. Soc. Exper. Biol. and Med.* 32: 538, 1934.

hepatitis, cirrhosis, abscess and carcinoma of the liver, as also in numerous cases of cholecystitis. They were thus led to the assumption that low liver diastase was found only in cases in which some form or other of liver damage and consequent impairment of liver function, was present. They claim that clinical observations as well as histological examinations, performed after operations and autopsies, fully support their theory. In some cases the low level of blood diastase directed attention to liver pathology before the existence of the clinical picture was revealed. Improvement of the hepatic condition after successful medical or surgical therapy was paralleled by the rise in blood diastase.

The Invasion Spreads

When the Federal Government embarked upon its extravagant program of hospital construction after the World War, the medical profession prophesied trouble. The less than two hundred thousand disabled who returned from France could easily have been handled in soldiers' homes and hospitals under the jurisdiction of the Army and U. S. Public Health Service. The erection of elaborate institutions all over the country provided a luscious melon for political favorites to divide, but it also raised the question of how to keep thousands of unnecessary beds filled.

The veterans' lobby, of course, had already prepared an answer. Taxpayers have been deprived of small comforts and even necessities to provide hospitalization for wealthy ex-service men suffering from ailments bearing no relation to their wartime duties.

The medical profession resents paying taxes to support hospitals that are in direct and unfair competition with its livelihood. From the outset it has feared that the Federal Government would be driven further and further into medical practice in order to justify the existence of these unnecessary institutions. Representative Stephen A. Rudd (Democrat, New York) gives substance to its fear with a bill he has recently introduced into Congress.

H. R. 43 requires the government to provide postal employees with free hospitalization for "tuberculosis, nervous diseases, or kindred occupational ailments." It does not explain how tuberculosis and nervous diseases came to be linked as "kindred occupational" risks of the Postal Service. Neither does it indicate what the other members of that hybrid pathological family are. Without reservation or qualification, Mr. Rudd offers every postal employee, regardless of earnings, free medical care in a government institution for an unspecified number of lesions.

Should H. R. 43 be enacted into law, the medical profession would have to pay additional taxes to have another large section of the public transferred from private practice to Federal care. A barrage of protests to Congress may serve to avert this injustice. Write or wire your representatives at Washington at once that the physicians of the country are unwilling to "hold the bag" for the misguided paternalism (or political maneuvering) of such bills as Mr. Rudd's.

Not Perfect but Desirable

It would be too much to expect that any one bill introduced into our Legislature would reach all the abuses which the profession desires corrected in the administration of the Workman's Compensation Law. There is a certain cohesive force among those whose interests would be disrupted, that makes for hurdles which no single act of legislation could surmount.

Reform therefore must be progressive and evolutionary. In the current legislative bill, however, there is much that is desirable.

The survey undertaken ten years ago by a Legislative Commission recommended as one way to correct abuses, that the Commissioner of Labor should have the advice and council of a medical board. Some of our County Societies opposed this, believing it was an effort to provide State jobs for certain physicians engaged in industrial work. The report of the medical committee headed by Dr. Pool nevertheless carried a recommendation for

a medical advisory board. There were intimations from labor, when the matter was under consideration last year, that it would be better if the Industrial Council were increased by adding to its membership a number of physicians, equal to the representations from labor and from industry. Then medicine would be represented adequately on the Industrial Council.

This one factor alone makes bill No. 19 desirable, but there are other desirable features in the legislation.

The county medical societies representing medical opinion in their respective localities, sooner or later will have to assume responsibility for the character and quality of medical services delivered to injured workmen. We stand for the free choice of the physician by the injured workman, and the county societies will be able to group and list their members as they are available for the work required. The county society is, by and large, composed of the reputable men of the community. There are physicians who will not want to do industrial medicine. Such need *not* be listed. Within the limits of those who are reputable and capable, free choice should be exercised.

The measure carries with it the implication, that for good cause, a name may be withdrawn from the lists by the county society. This feature permits the maintenance of standards of quality. On the other hand, it will be the function of the

county society to enact By-Laws that will give every member, and even those reputable men who *may not belong to organized medicine*, every possible protection and safeguard.

As a result of this, it will be found that the county societies will gradually broaden their scope. At present they are concerned with the protection of the public generally, but when this legislation will have been enacted, they will have to protect ALL physicians in the county who are of good repute and standing, and competent to do the work.

We have never believed in the establishment of a fee schedule. The prevailing fees in any particular community for similar work, we hold, should be the basis of pay.

Conditions differ in industrial areas from those in metropolitan New York City and from both in rural sections. It is desirable therefore, that the county societies shall determine whether clinics shall be established and how they shall function.

By all means, let us back up our committee in support of bill No. 19 to the end that by proper representation on the Industrial Council a real start will have been made in reforms which are so necessary to stop exploitation of labor; to stop discrimination against physicians who desire to do industrial surgery and who are now kept from this work; and to establish control over quality of services rendered.

Special Medical Broadcast Program

The American Medical Association will broadcast on a special program arranged through the courtesy of the National Broadcasting Company over a network of stations, beginning at 6:00 P.M., eastern standard time, Monday, February 18. The program will include music and three speakers from among physicians in attendance at the Annual Congress on Medical Education and Medical Licensure, meeting in Chicago on that day. The speakers will be introduced by Dr. Morris Fishbein. The speakers and their topics are as follows: "Advancement of Medical Education," Walter L. Bierring, M.D.; "The Prolongation of Life," Ray Lyman Wilbur, M.D.; "The Battle Against Tuberculosis," Kendall Emerson, M.D.

Drug Addiction as a Medical Problem

Ossining, N. Y.

To the Editor:

In the December 15, 1934, issue of the *New York Medical Week* appeared an editorial entitled "Reform for Its Own Sake," which stimulated me to send to *Medical Week* a letter in opposition to the stand taken by the editorial. Unfortunately, my reply was of such length that *Medical Week*, could not find the space required for its publication.

Medical Week suggested that I seek your larger columns for presentation of my views in a matter that seems to me to deserve wide and thoughtful consideration by the profession. I hope you may find some way to place before the members of the State Society both the editorial and my reply.

That editorial reads as follows:

"If all the reforms advocated by many sincere but ill-informed persons were laid end to end—it is more than likely that they would lead nowhere. The Welfare Council's Committee on Chronic Illness has recently released a report on drug addiction which is typical of the alacrity with which many social crusades proceed from a mistaken hypothesis. Designating narcotism as a chronic disease, Miss Mary C. Jarrett has no difficulty in arriving at a solution in the form of therapeutic farms. This would be an easy answer to a difficult question if drug habituation were essentially a medical problem. Unfortunately, it is not.

"While present police regulations are undoubtedly archaic and there is inadequate provision for the care of addicts desiring treatment, the fact remains that most authorities consider narcotism essentially a criminal problem and there is no satisfactory medical cure. The only way to put an end to drug addiction is to prevent it—and the only way to prevent it is to cut off the illicit vendor from his source of supply. Until the nations agree to limit the production of habit-forming drugs to medicinal and industrial requirements, there is little hope of curbing narcotism. Therapeutic farms are indeed a palliative but not much can be hoped from them in the way of either prevention or cure."

My response is:

Your editorial strikes a note that leads me to comment. I would preface my remarks with the statement that I am not an advocate for the social workers. In fact, I am so far opposed to their philosophy and point of view as to feel quite out of harmony with the present national administration which appears to me to be a "social workers' administration." I believe that time will put

its mark of disapproval upon the "social workers' administration" just as it already has done on the "chamber of commerce administration" of ex-President Hoover, upon the "noble experiment," and other social procedures in which over 100 million people are used as guinea-pigs for experiments in social control and social reform. "Rugged individualism" has failed; the present régime of subtotal elimination of individual initiative will fail in this country just as the total elimination has failed in other countries already.

I hope that the paragraph above will give the intended impression that I am no particular friend of the "social work point of view." However, in the present instance, I believe that Miss Mary C. Jarrett has arrived at a valid conclusion in her two-volume work on Chronic Illness (which I have read from cover to cover, by the way) when she classifies drug addiction with chronic illness.

To jump from diagnosis to management or treatment of the condition is possible in only a few diseases and certainly is not possible in so complicated a problem as that of drug habituation. Of course, this jump is quite characteristic of social worker management, with rare exceptions. In this, I am opposed to Miss Jarrett's recommendation. At the same time, it appears to me that this jump is the subconscious origin of the editor's indignation which has given rise to the editorial; he has a valid, a kind of "righteous" indignation. The gap, the hiatus is too glaring; the chasm is too appalling—he cannot straddle it.

Yet, with all his emotional conflict, it is worthy of note that the editorial writer admits that "therapeutic farms are indeed a palliative . . ." Just at this point he leaves an opening in his defenses. I want to attack at this point. I am sure that the editor will admit that he has to use palliative management in the handling of some of his private hospital cases. He does not neglect them entirely, just because his palliative procedures do not give him much hope in the way of either prevention or cure (using the editor's own words).

This editorial also uses a glaring phraseology which I wish to dispute. It is as follows: ". . . if drug habituation were essentially a medical problem. Unfortunately, it is not." A companion statement is ". . .

most authorities consider narcotism essentially a criminal problem. . . ." These two I would dispute together.

First, as to whether drug habituation is essentially a medical problem or not, I have to beg your indulgence to grant that psychiatry is a branch of medicine. If you grant me this point without claiming that I am begging the question, I think you have lost your case, because there is no doubt in the minds of the psychiatrists, that narcotism is a psychiatric problem. Those who have made adequate psychiatric examinations of any considerable number of narcotic addicts are convinced that these unfortunates are filled with unsolved personality problems, conflicts, repressions, et cetera, which we also find in a great many other types of personality deviates. That this is a fact can not be refuted today with success.

Of course, this does not mean that we know all about the mentality of the addict. We still would like to be able to explain why, with a given set of psychological conflicts, and so on, one group of youths works out to normality without outside help, apparently in the course of the process of normal growth and development, while another group becomes addicted to narcotics, another becomes addicted to alcohol, another becomes perverted, another becomes criminal, and still another becomes floridly psycho-neurotic, while some few belong in several groups.

I will claim that we now have a number of ideas and theories as to why these differences exist in the "working out" of a given set of conditions, while I admit, at the same time, that much still remains to be learned and determined with certainty. I can not go into the matter deeply in a brief discussion of this type.

If you will admit, for the purposes of argument, that drug habituation is a psychiatric problem and that psychiatry is a branch of medicine, it follows naturally that you will have to withdraw from your position that drug habituation is not a medical problem.

If you will grant me this advantage I will press another point upon your attention. The therapeutic farm idea isn't so bad after all! Now, I am eager to state that a therapeutic farm operated under social service ideals would indeed be only a palliative, as your editorial claims but I am equally strongly of the opinion that a therapeutic farm operated under psychiatric control might be a successful venture. The duty and responsibility will rest upon the psychiatric profession to supply adequate personnel for such an undertaking. Such personnel would have to be trained in general medicine, in institutional psychiatry, in mental hygiene

clinics or child guidance clinics and in juvenile and adult court psychiatric clinics.

In addition, these psychiatrists would have to be gifted for this particular type of understanding; it is an art—not a science, though assisted by many sciences. They would have to be familiar with psychoanalytic principles and ought to be psychoanalyzed themselves as a prerequisite, unless they have been able to work out their own personality problems to a fairly normal conclusion. So much for "therapeutic farms"; if they can be made really therapeutic in a psychiatric way, all well and good; if social service controls the therapy, the point is that therapy belongs to the field of medicine and social service is not equipped nor legally licensed to practice therapeutics.

I want to answer your editor's "legal argument," too; that "most authorities consider narcotism essentially a criminal problem . . ." That is true. To regard abnormal behavior as criminal is an easy way to bring such behavior under social control. No one disputes that the public welfare (group welfare) must control individual conduct. No one may live where others live and still conduct himself as if those others did not exist. That is one bit of ethical theory and moral conduct that is biologically well founded. But, I would point out again what is already well known and that is, that the insane were regarded as criminal until very recent times, even after the many centuries when they were called "possessed of demons."

As late as 1906, the insane could be taken from the State Hospital in Rhode Island on a bail bond, contingent upon their good behavior. I infer what we all know; that the label of "crime" is largely a matter of time and place; era and circumstance. Even in New York till recently, suicide was punishable as a crime. Granting that to label a specific type of conduct as criminal is a means of social control, it is an expedient, dictated by necessity and to be changed when times are suitable for such orderly transition.

With regard to the editor's suggestion that "the only way to put an end to drug addiction is to prevent it—and the only way to prevent it is to cut off the illicit vendor from his source of supply," I feel rather diffident. The editor's net sentence is just too much. It is as follows: "Until the nations agree to limit the production of habit forming drugs to medicinal and industrial requirements, there is little hope of curbing narcotism." [*sic*] If this is really the state of affairs, we may as well put up with the problem; grin and bear it. The nations never yet have agreed on anything for very long. When things seem fairly well settled, some nation or other feels that the agree-

ment is merely another "scrap of paper" and proceeds to make it such. Among equals there is no master and it would seem that among nations there is very little more guidance by eternal principles than there is among individuals, sometimes it is questionable whether there is as much. Even among individuals, it is difficult to get agreement and it is impossible to maintain it.

It occurs to me that our experience with the Volstead Amendment ought to refute the statements of the editor which I have just quoted. There were some people who thought that "the only way to put an end to alcoholic addiction is to prevent it—and the only way to prevent it is to cut off the supply." What a miserable failure that was! To attempt to cut off the supply of drugs would be just as impracticable. The *Encyclopedia Britannica* states that opium may be produced wherever the climate is temperate or subtropical and the rainfall is not excessive. It has been produced in Virginia, Tennessee, and California, only the cost of labor made it unprofitable. Such being the situation, we are in a position, in this particular, as we were to try to prevent disease by shutting off the supply of bacteria.

The simile I have used is not so far-fetched as it may appear to be on the surface. The comparison I would draw is that we have found in the case of the infectious diseases that we may, at least, immunize the individual since we can not shut off the supply of bacteria completely. We can do a similar thing, I believe, in the case of the prevention of drug addiction. Remember that I am using a simile and allow me to proceed.

We psychiatrists know that the addict is a hypersensitive sort of creature on the average. He can not face reality. The world is too tough for him. His addiction forms an escape from reality—often into temporary oblivion. That narcotic is a crutch, it is a means of support psychologically, he loves it, it is his sole defense against a cruel world of harsh reality. The addict is an immature person emotionally, he is often unstable. He is inferior and his inferiority comes out in his personality makeup in myriad ways. He is usually weak, suggestible, and inadequate. In many ways, without being insane, his personality is introverted, schizoid, and sometimes paranoid. If he were not a drug addict he would be an alcoholic, a pervert, a criminal, or a psychoneurotic. He frequently passes through several of these phases. Some become insane, few ever become normal.

What causes some persons to become addicts while others become normal when both had similar beginnings is one of the many fascinating problems of psychiatry that still remains unsolved. I contend that the first step in the solution of the problem is to

recognize drug addiction as a psychiatric problem—medical, if you please! Of course, we can go through the usual stages. Let religion handle the problem first. Then let the law take it in hand, that's where it is now. Then let the social workers (public welfare) take charge of it and then, when everybody admits that it is not their problem, let the psychiatrists have it. That has been the course of history with the insane and the alcoholics. Now come the drug addicts, the perverts, and the criminals.

I, for one, am in favor of therapeutic farms for narcotic addicts even if a social worker did propose it. As outlined above, my suggestion is that the therapeutic part be placed in the hands of psychiatrists competent to analyze these personalities and to desensitize them, physiologically, if possible. It would take only a slight change in the Mental Hygiene Law to provide the legal machinery. The public funds which now support these addicts as "unemployables" would meet the expense of operation. Properly chosen land, properly worked, as well as shops for necessities would make the group almost entirely self-supporting.

In conclusion I would apologize for the wide range and diffuseness of this reply. In comparison with the succinct way in which the editor has said so much in so little space, I feel that what I have written needs defense. My defense is that the editorial is too important to pass over without comment and too thought-provoking to be discussed in a few words.

Finally, as to my own position in the matter, I am writing as an individual. These are my personal views, I alone am responsible for them, without assuming to speak for any of my colleagues. My position with regard to this discussion is that of a private citizen and not that of an official or public servant.

HAROLD I. GOSLINE, M.D.

Original Use of Buffer Salts as a Pharmacological Agent

90 Riverside Drive, New York City

To the Editor:

There appeared in the *NEW YORK STATE JOURNAL OF MEDICINE* an article on March 1, 1934, on "A New Intravenous Therapeutic Agent for the Control of Peptic Ulcer," which described the use of a solution, the composition of which is given in detail in the issue of June 15, 1934, in connection with an admission of the authors, of their failure to include the complete bibliography in connection with the use of this substance in gastric and duodenal ulcer. To describe this therapeutic agent as new is in this instance entirely unwarranted. The fact that

a solution whose composition is *basically the same* as that described was published nine years previous to the present publication is sufficient to invalidate the claim of originality. Furthermore, the description of the basic principles involved, ignoring as it does the original contribution, is inexcusable, to say the least.

A perusal of the article by Butman *et al.* would give the impression that this solution was originated by L. J. Schultz, when as a matter of fact a solution of practically the same composition had been used in the treatment of thromboangitis obliterans since the middle of 1921. This article published by Butman, Schultz, and VanKleeck in no way suggests that the use of this solution was based upon work done in my laboratory by one of the authors, and omits specific mention of its origin either in the article referred to, or in the subsequent note regarding its composition appearing in June 15, 1934.

This letter is not written with the desire to claim exclusive priority for the introduction of this solution but simply to emphasize the essential lack of consideration evident in the article referred to. In a communication published in the *Journal of Laboratory and Clinical Medicine* on "The Use of Buffer Citrate Solution as a Diluent and Preservative for Red Blood Cells," written at my suggestion by L. J. Schultz, who worked in my laboratory, a description of this solution is furnished which corresponds to the description appearing in the article in *International Clinics* in September, 1925. In that article the fact is definitely stated that this solution was being used by myself, and that the effects were being observed upon patients in my practice. The work on red blood cells was carried out at my suggestion.

Under the circumstances, I feel that any further work in connection with this solution should at least mention the fact that the use of certain buffer salts in connection with sodium citrate and sodium chloride as a pharmacological agent for the treatment of various conditions was original with me.

BENJAMIN JABLONS, M.D.

Child Labor a Social and Industrial Malignancy

694 Miller Ave., Brooklyn.

To the Editor:

Reading the editorial on the proposed Child Labor Amendment, ["Elementary Rights of Children and the proposed Child-Labor Amendment," January 1, 1934] one is apt to be misled by its obtuse generalities, its unreasoning prejudices and its mawkish sentimentality.

According to you our Congress is the agency of Moscow and all legislation emanating from the congressional halls, a heinous plot to sovietize American institutions. Conversely, you portray the various state legislatures as the only genuine patriotic bodies capable of passing upon Child Labor problems. To the physician willing to weigh facts your contention is full of buncombe. No rational individual will believe for a moment that Congress is trying to snatch children away from their mothers to the detriment of the American home. This is the tripe which various organizations interested in exploiting child labor are doling out to the unwary.

You do not mention that various States are trying to attract industry by the lure of cheap child labor, and that a Federal law would put a stop to this rapacious form of human exploitation and unfair industrial competition. Instead you becloud the issue by dragging in the Red bogeyman and exhibit misdirected anguish at the plight of children under a bureaucratic form of sovietism. Offering the assistance of the medical profession is wholly beside the point and sugary platitudes can in no way remove a nasty irritation to our present colicky economic situation. Child Labor is a social and industrial malignancy and the treatment of it is radical excision. The Federal Amendment is the scalpel for this operation. To allow Child Labor to survive in any state is to expose the national organism to a definite menace.

GEORGE S. MEISTER, M.D.

NEW SERUM FOR UNDULANT FEVER

A report of twenty undulant fever patients who made prompt recovery to health and normal activity following the use of a new serum was made to the American Society of Tropical Medicine, which met in San Antonio last month. The serum was produced from goats after inoculating them with chemically treated suspensions of the causative organism, *Bacterium melitensis*.

Drs. W. D. Wherry, A. E. O'Neil, and Lee Foshay, of the University of Cincinnati

College of Medicine and of the Cincinnati General Hospital, are the group responsible for this advance in the fight against undulant fever.

Doctor (examining East Side brunette):
"You have got acute appendicitis."

Patient: "Don't get fresh! I came here to be examined—not admired."—*Nebraska State Medical Journal*.

Society Activities

COMMITTEE ON LEGISLATION

BULLETIN NO. 2, JANUARY 15, 1935

The following bills have been introduced since the last bulletin:

Senate Int. 123, Esquirol; Assembly Int. 150, McCaffrey; Assembly Int. 210, Neustein, amends the Workmen's Compensation Law relative to physical examination of employees by striking out provision that physician, as employee or carrier may select and pay for, may participate in examination if employee or carrier so request. Referred to the Labor Committee.

Senator Esquirol introduced this bill last year but failed to have it reported by the committee. We were never able to understand just why it was not advanced. In our conversations with representatives of organized labor we thought that they approved the bill. It provides that an injured employee, claiming or entitled to compensation, shall submit to such physical examination as the Commissioner or the Board may require and deletes the following: "Such physician or physicians as the employee or carrier may select and pay for, may participate in an examination if the employee or carrier so requests." Labor has frequently complained that the presence of the carrier's physician at the examination of an injured employee by the Department of Labor's physician, is not desirable.

Senate Int. 154, Schwartzwald; Assembly Int. 196, Doyle, amends the Health Law by providing reports of infections, contagious or communicable diseases must be made to the health officer of city, town, or village from which specimen came, requirement to report also to place where laboratory is situated being stricken out. Referred to the Health Committee.

This bill was introduced at the request of the Department of Health. It deletes from the law some sections which have become obsolete.

Senate Int. 203, Berg, creates state commission of 15 members to investigate illegal practice of professions now regulated by law and to examine and recommend changes in laws governing professions, and appropriating \$50,000. Referred to the Finance Committee.

We have had no opportunity of discussing with the Senator the reason for his introducing this bill.

Senate Int. 208, Byrne, Lien Law, for liens of hospitals, physicians, and nurses for care and treatment of certain injured persons. Referred to the Judiciary Committee.

Senator Byrne has reintroduced his hospital lien bill of last year, the one which passed the Senate.

Senate Int. 246, Wicks, adds new article to the State Charities Law abolishing Temporary Emergency Relief Administration and transferring on July 1, 1936, all powers and duties thereof to the Social Welfare Department to be exercised by a division of unemployment relief. Referred to the Relief and Welfare Committee.

There is a commission that was appointed by the Governor to study the administration of the temporary emergency relief funds. The commission will in the near future make a report of progress to the Governor but it is not likely to finish its study in time for consideration by this Legislature.

Assembly Int. 123, Breitbart, adds new section to the Civil Practice Act empowering courts in personal injury actions to direct any party or child of such party to submit to one or more blood tests. Referred to the Codes Committee.

Assembly Int. 166, Breitbart, amends the New York City Inferior Criminal Courts Act by authorizing court to direct the making of blood tests and permitting the results thereof to be received in evidence. Referred to the Codes Committee.

These bills are introduced for the purpose of giving authority to hospitals when they wish to employ the blood test to determine paternity, we are informed by Mr. Breitbart.

Assembly Int. 185, G. W. Stewart, amends the Education Law relative to supervision of clinical laboratories by persons licensed to practice medicine. Referred to the Education Committee.

Mr. Stewart has reintroduced his bill of last year. He also is preparing for introduction a bill submitted to him by us which includes x-ray laboratories.

ACTION ON BILLS

Senate Int. 45, Fearon, reorganization of county government, has passed the Senate and reached third reading in the Assembly.

HEARINGS

Jan. 23—Sen. No. 18
Assent. No. 18

Workmen's Compensation; exclusive State Fund; joint hearing before Committees on Insurance.

- Jan. 23—Sen. No. 19
Assem. No. 19 } Workmen's Compensation; medical abuses; joint hearing before Committees on Ways and Means, Judiciary and Labor.
- Jan. 29—Sen. No. 20
Assem. No. 20 } Workmen's Compensation; occupational diseases; joint hearing before Committees on Labor and Industry.

We are informed that insurance companies and insurance agents are soliciting the interest of physicians in opposing Senate and Assembly bills No. 18, the creation of an exclusive State Insurance Fund. As you are aware, it is our intention to oppose the advancement of these bills. We are pleased to have this opportunity of co-operating in opposing the bills, but it is well to remember that our friends, the insurance companies and agents, are the principal ones opposing the advancement of our hospital and physician lien bill. We recommend, therefore, that before pledging your co-operation, you ask them, in return, to withdraw their opposition to the lien bill.

BULLETIN NO. 3, JANUARY 24, 1935

The following bills have been introduced since the issuance of the last bulletin:

Senate Int. 270, Schwartzwald; Assembly Int. 199, Doyle, amends the County Law by empowering supervisors, except in a county constituting a general health district, to employ dentists as well as health nurses, etc. Referred to the Internal Affairs Committee.

This bill was introduced at the suggestion of the Department of Health.

Senate Int. 271, Schwartzwald; Assembly Int. 194, Doyle, amends the Public Health Law by empowering the health commissioner to order reasonable improvements for protection of water supplies found to be inadequate or of such objectionable quality as to constitute a menace to public health. Referred to the Health Committee.

This bill was introduced at the suggestion of the Department of Health.

Senate Int. 302, Twomey; Assembly Int. 498, Alterman, Public Health and State Finance Laws, authorizing the health commissioner to administer any grant, gift or bequest to be applied to maintenance and use of any hospital, institution or service in Health Department, all such grants and bequests to be paid to Taxation Department to be held there in trust. Referred to the Health Committee.

The Department of Health has had this bill introduced to give it legal authority to accept and dispense funds that may be offered for public health activities; as, for instance, at present the Rockefeller Founda-

tion offers financial assistance for the development of certain public health units.

Senate Int. 321, Esquirol; Assembly Int. 131, Breitbart, amends the Decedent Estate Law by providing an action for personal injuries may be brought after death of injured person or continued by his executors against the wrongdoer. Referred to the Judiciary Committee.

Senate Int. 357, Byrne; Assembly Int. 445, McDermott, adds new article to the Agriculture and Markets Law for governing sale and distribution of lye and other caustic substances in containers for household use. Referred to the Agriculture Committee.

This bill has been before the Legislature for a number of years. It is opposed principally by merchants who handle disinfectants.

Senate Int. 365, Crawford, amends the Civil Service Law by providing no person shall be appointed to position in classified service unless he is a citizen of the United States and has resided in state for at least two years, but such requirements may be waived for any individual or group if positions are in exempt or non-competitive class and if public interest demands such waivers. Referred to the Civil Service Committee.

Senate Int. 401, Esquirol; Assembly Int. 489, G. W. Stewart, adds new section to the Penal Law prohibiting sale of appliances, drugs or medicinal preparations for prevention of venereal diseases or used in gynecological hygiene, or advertisement or display thereof, except in places registered by State Pharmacy Board. Referred to the Codes Committee.

This bill was introduced at the suggestion of the Pharmaceutical Association. Preparations and apparatus of this kind are articles of trade, found at many places other than drug stores; for instance, gasoline stations, florists, beauty parlors, cigar stores, way-side lunches, and so on.

Senate Int. 409, Kleinfeld; Assembly Int. 551, Marasco, adds new section to the Education Law providing portion of street in front of physician's residence in each city or town shall be reserved as parking space for exclusive use of himself and persons visiting him professionally. Referred to the Education Committee.

The necessity for a law of this kind demands no argument.

Assembly Int. 321, Doyle, amends the Public Health Law by permitting a city at any time after three years to withdraw from a county health district; also providing that public health nurses must be qualified under regulation of Public Health Council, and for election of a vice-president as well as president of a county health board. Referred to the Health Committee.

This bill was introduced at the direction of the Department of Health.

Assembly Int. 344, W. Schwartz, amends the Public Welfare Law by reducing from 70 to 65 years, age at which person may

qualify for old-age relief. Referred to the Relief and Welfare Committee.

Another old-age pension bill which does not differ materially from those reported before.

Assembly Int. 371, Doyle, adds new section to the Lien Law for liens of physicians for care and treatment of persons injured as result of negligence of any other person or corporation. Referred to the Judiciary Committee.

This is the physicians' lien bill which the Committee on Legislation prepared and asked Mr. Doyle to introduce. The bill is identical with the Byrne bill (Senate Int. 208) except that it provides for physicians alone; hospitals and nurses are not included.

Assembly Int. 372, Doyle, amends the Health Law by providing at least two of six appointive members of the Public Health Council shall be physicians engaged in active clinical practice of medicine for at least five years prior to appointment. Referred to the Health Committee.

This bill was also prepared by the Committee on Legislation and introduced by Mr. Doyle at its request. It will be recalled that the House of Delegates instructed it to do so.

Assembly Int. 452, Rossi, adds new article to the Public Welfare Law establishing an old-age security fund consisting of contributions by members of fund, employers of labor, by gift or legacy, together with deficiency contributions by state and contributions by the United States Government; fund to be administered by board of state welfare commissioner, insurance superintendent, Attorney General, and two persons appointed by Governor, annuity to be \$50 a month on attaining age of 65 years. Referred to the Relief and Welfare Committee.

Another unemployment bill. It differs slightly from the others, particularly in the amount of the annuity.

Assembly Int. 461, G. W. Stewart, amends the Education Law by defining "laboratory," "clinical laboratory," "x-ray laboratory," for purpose of supervision and excepting therefrom qualitative or quantitative analysis of urine by a licensed pharmacist, and making certain other exceptions. Referred to the Education Committee.

This is the clinical laboratory bill that the Committee on Legislation prepared. It is similar to the other clinical laboratory bill except that it includes x-ray laboratories.

Assembly Int. 558, Sullivan, adds new section to the Labor Law making 8 consecutive hours in any 24 a legal day's work for nurses in public hospitals or hospitals supported in whole or in part by public funds. Referred to the Labor Committee.

Assembly Int. 559, Sullivan, amends the Public Welfare Law by requiring public welfare districts to give necessary medical care for all persons "making application"

and requiring appointment of an appropriate number of physicians for such purpose, on fixed salary, notwithstanding any restrictions in the Public Welfare Law. Referred to the Relief and Welfare Committee.

This amendment would make it almost necessary that boards of supervisors or other appointing bodies employ physicians for welfare work on salary rather than by the case method. Each year some attempt of this character is made. The law now does not prevent the appointment of physicians on contract or salary basis, but it specifically favors the case method, which provides the family with the services of its chosen physician.

May we recommend that every person receiving this bulletin advise his legislators regarding the action they should take upon these bills. Please advise upon all of them. If you need further information before you take action, we shall be glad to do what we can to inform you; but it is important that the legislators know the opinion of their constituents when they are called upon to vote, and again we remind you that the Legislature is acting very expeditiously this year. There is no time for delay; some of these bills are exceedingly far-reaching and will affect the practice of medicine materially. When you are writing, we would consider it a great favor to have copies of your letters sent to our Legislative Bureau.

HEARINGS

Jan. 29 — Sen. 20 — {Occupational disease
Coughlin bill; hearing before
Assem. 20—McCaffrey } Joint Committees on
Labor and Industry.

Hearings were held yesterday on bills No. 18 and No. 19, the compulsory State Insurance Fund and medical abuses bills, respectively. Enormous crowds filled the Assembly chamber in opposition to the State Insurance Fund proposition. Its only proponents were the Department of Labor and organized labor. The arguments presented against the bill appeared to us very damaging and it seems altogether unlikely that the bill will be advanced in its present form.

In the Senate chamber, where the hearing on medical abuses was held, the Committee first listened to arguments pro and con on the child labor amendment to the Constitution. Arguments were very spirited and lengthy; the hearing did not close until 7:30 p.m. and it was immediately followed by the hearing on the medical abuses bill, which did not terminate until after midnight.

Opponents of this bill were representatives of the Clinical Laboratory Association, the Public Health Laboratory Association, Associated Industries, and insurance companies.

(Continued on page 139)

Current Comment

President Roosevelt's message to Congress on Social Security, on January 17, said: "I am not at this time recommending the adoption of so-called health insurance, although groups representing the medical profession are co-operating with the Federal Government in the further study of the subject and definite progress is being made."

A message on this topic is indicated as due about March.

As we go to press, news from Albany would seem to indicate that the bill confining Workmen's Compensation Insurance to the State Insurance Fund and self-insurers, and which would deprive all private insurance companies of this business, will not pass. The profession, as well as other interested parties, have objected to its enactment.

If the wage deductions necessary for the old age pension program of President Roosevelt is added to the wage deduction that the intended Health Insurance program would necessitate, the wage-earner would find it necessary, either to lower his standard of living, or to ask for a wage increase! When the contributions of employers are considered, an added wage increase would make for the increase in the costs of commodities to the public. There are implications in all this that require more deliberation than just the few weeks that the public hearings on these measures permit. Whither are we heading?

Compulsory Health Insurance Cat Now Out of the Bag

The health insurance bill that is to be presented to Congress and to the 43 State legislatures now convening, and railroaded through them if possible, is out in the open, and it can now be seen what the socializers of medical care propose.

Lawmakers at Washington and at the various state capitals will now be told what to think, how to vote. The bill is the work of the "American Association for Social Security," with offices at 22 East 17th Street, New York City. Among its officers are Miss Jane Addams, Bishop Francis J. McConnell, Alfred I. DuPont, Glenn Frank, John A. Lapp, I. M. Rubinow, and Herbert S. Bigelow. The bill itself was drawn up by Prof. H. A. Gray of the New York University Law School, assisted by Edwin E. Witte, secretary of the President's Committee on Social Security, and by Abraham Epstein, executive secretary of the New York

association. On the advisory committee were two doctors—not engaged in general practice—Dr. Haven Emerson and Dr. Alice Hamilton.

Essentially, the bill provides compulsory health insurance for the great proportion of those earning less than \$3,000 a year. In case of illness, they would receive cash benefits for disability, maternity benefits, and medical benefits. The medical benefits would include the service of a general practitioner, general and special hospital treatment, nursing care, surgical treatment, dental treatment, and services of laboratories and clinics. The physicians, hospitals, and so on, are to be selected by the patient from a list of those willing to serve, and the physicians of each locality, by majority vote, would determine the method of their compensation.

The administrative machinery which is to run the scheme provides for a network of paid appointees that may well make politicians smile and taxpayers gasp. First there would be a state health insurance commission, with advisory councils, boards of adjustment and appeal, clerical force, and what not. Then the state would be divided into districts, with district councils, boards, committees, clerical force, and so on, and under them would be the local offices, with local medical and financial agents, inspectors, and workers. The cost of all this machinery for a state like New York would be terrific, all on the plea of reducing the cost of medical care!

Funds for financing the scheme are to be raised by compulsory contributions from the employed, the employer and the state, varying with the scale of the worker's pay. The three contributions together would amount to 6 per cent of the worker's wages. It need hardly be said that a golden tide of 6 per cent of the worker's pay of New York State rolling into a central fund annually is enough to make the politicians' mouths water.

The final object of all this is to let Frank Hogan, when he is sick, go to a clinic or hospital, or to Dr. Smith's office, and have the medical care he needs—exactly what he does now, without all the maze of job-holders provided by his bill. If the cost is to be cheaper than now, where is the difference to be taken out? The answer is as clear as daylight. There is only one place where it can come out, and that is out of the doctor. The doctor will be systematized and machinized to the point where he will be seeing patients as fast as they can pass through his hands, at a pittance each, under the orders of a political superintendent or inspector who can perhaps ruin his prac-

tice if he votes the wrong ticket or fails to contribute enough to the party treasury. This congestion of patients into a few hands, too, can only mean that doctors who are out of favor will also be out of luck, and while some are overcrowded, others will have little or nothing to do. The present plan of fair and honest competition, where each doctor gets what he is able to win, is certainly more American and more likely to give both doctor and patient the best results.

There have been no reports of mass meetings or petitions of wage workers asking for any scheme of this kind, and the general feeling of the medical profession is flatly against it. It seems to be hatched from the brains of the managerial meddlers who are bent on running the country and imposing hare-brained ideas that used to engage the imaginations of high-school debaters. If the lawmakers are informed of the wishes of the doctors in this matter, no doubt it may be shelved, but if nothing is done, it may get by, and great damage may be done.

The issue is joined. The war is on. Opposition to the measure has been recorded not only in New York State but in many other States.

Motor Crashes That Injure the Doctor

If one peers about among the wreckage of a motor smash-up, one will not usually see a doctor lying there with a broken leg or with scrambled interior arrangements, but he is often among the injured, for all that. The victims are rushed to the hospital or to the doctor's office, the medical man gives of his time and skill, lives or limbs are saved, and then the doctor is blandly told: "It was the other fellow's fault. Send your bill to him." So the final sufferer is the doctor, who gets his injury in healing that of the victim.

Some people seem to think that insurance covers everything, but the fact is, that only 25 per cent of the automobiles in this country are covered by liability insurance. A moment's thought, too, will show that this does not mean that one-quarter of all accidents are covered by insurance, for two cars usually figure in every wreck, and the likelihood that both are in the list of insured whittles down to a slim chance. The probabilities are good (or bad) that the doctor will have no recourse to insurance whatever. A good plan is to secure the license numbers of both cars from the police and file a claim with both parties at the earliest date possible—then the doctor will figure in any settlement made, and will at least have as good a chance as the mechanics who straighten the fender or tow the wreck to the dump. They always get their pay; why shouldn't the doctor have his as well?

In cases covered by insurance policies, a plan has been perfected in Indiana to protect the doctor's interests, formulated by joint committees representing the insurance companies and the State Medical Association. Under this plan a form has been drawn up, to be signed by the injured party, ordering the insurance company, in case a cash settlement is made on account of his injuries, to pay the doctor's bill. The physician, as soon as the amount due for his services can be figured, presents the order to the insurance company and, if all is in order, the bill is paid.

Furthermore, to lubricate the friction of misunderstanding with the oil of goodwill, a standing committee representing both the insurance and the medical interests has been set up to heal any conflicts and grievances that may arise. The plan has been in operation for two years, and the chief complaint is that too few of the doctors avail themselves of it.

It is at least clear from this Indiana instance that the insurance companies stand ready to do all they can to help the doctors recover their just dues for their services. They will, in fact, be wise to do so, for when the doctor saves a life or heals what would be a crippling injury, he saves the insurance company the payment of damages that might run into high figures. Motorists and insurance companies alike will do well to see to it that the medical man is honestly paid for repairing the human wreckage in these motor crashes. His modest fees represent a small fraction indeed of the value of his services. True, there is not the slightest danger that he will ever go on strike or refuse to aid the injured, but it seems scarcely necessary to say that it will be worse than foolish to do what is too often done now—accept his services and then leave him cheated and injured financially.

Medico-Dental Teaching—Graduate and Undergraduate

The fourth annual Joint Medical-Dental Meeting, arranged by the five County Medical Societies and the two District Dental Societies of New York City, was held on December 3, 1934, under the auspices of the "Better Dentistry Meeting." The morning session was devoted to a consideration of present arrangements in medical schools and dental schools for teaching of conditions with both oral and systemic phases. The term "Medico-Dental Teaching" has grown into use to indicate this type of professional education.

At the session, the Secretary of the Joint Committee in charge, Dr. M. O. Magid, gave a brief description of the inception of combined meetings between the two professions,

Current Comment

President Roosevelt's message to Congress on Social Security, on January 17, said: "I am not at this time recommending the adoption of so-called health insurance, although groups representing the medical profession are co-operating with the Federal Government in the further study of the subject and definite progress is being made."

A message on this topic is indicated as due about March.

As we go to press, news from Albany would seem to indicate that the bill confining Workmen's Compensation Insurance to the State Insurance Fund and self-insurers, and which would deprive all private insurance companies of this business, will not pass. The profession, as well as other interested parties, have objected to its enactment.

If the wage deductions necessary for the old age pension program of President Roosevelt is added to the wage deduction that the intended Health Insurance program would necessitate, the wage-earner would find it necessary, either to lower his standard of living, or to ask for a wage increase! When the contributions of employers are considered, an added wage increase would make for the increase in the costs of commodities to the public. There are implications in all this that require more deliberation than just the few weeks that the public hearings on these measures permit. Whither are we heading?

Compulsory Health Insurance Cat Now Out of the Bag

The health insurance bill that is to be presented to Congress and to the 43 State legislatures now convening, and railroaded through them if possible, is out in the open, and it can now be seen what the socializers of medical care propose.

Lawmakers at Washington and at the various state capitals will now be told what to think, how to vote. The bill is the work of the "American Association for Social Security," with offices at 22 East 17th Street, New York City. Among its officers are Miss Jane Addams, Bishop Francis J. McConnell, Alfred I. DuPont, Glenn Frank, John A. Lapp, I. M. Rubinow, and Herbert S. Bigelow. The bill itself was drawn up by Prof. H. A. Gray of the New York University Law School, assisted by Edwin E. Witte, secretary of the President's Committee on Social Security, and by Abraham Epstein, executive secretary of the New York

association. On the advisory committee were two doctors—not engaged in general practice—Dr. Haven Emerson and Dr. Alice Hamilton.

Essentially, the bill provides compulsory health insurance for the great proportion of those earning less than \$3,000 a year. In case of illness, they would receive cash benefits for disability, maternity benefits, and medical benefits. The medical benefits would include the service of a general practitioner, general and special hospital treatment, nursing care, surgical treatment, dental treatment, and services of laboratories and clinics. The physicians, hospitals, and so on, are to be selected by the patient from a list of those willing to serve, and the physicians of each locality, by majority vote, would determine the method of their compensation.

The administrative machinery which is to run the scheme provides for a network of paid appointees that may well make politicians smile and taxpayers gasp. First there would be a state health insurance commission, with advisory councils, boards of adjustment and appeal, clerical force, and what not. Then the state would be divided into districts, with district councils, boards, committees, clerical force, and so on, and under them would be the local offices, with local medical and financial agents, inspectors, and workers. The cost of all this machinery for a state like New York would be terrific, all on the plea of reducing the cost of medical care!

Funds for financing the scheme are to be raised by compulsory contributions from the employed, the employer and the state, varying with the scale of the worker's pay. The three contributions together would amount to 6 per cent of the worker's wages. It need hardly be said that a golden tide of 6 per cent of the worker's pay of New York State rolling into a central fund annually is enough to make the politicians' mouths water.

The final object of all this is to let Frank Hogan, when he is sick, go to a clinic or hospital, or to Dr. Smith's office, and have the medical care he needs—exactly what he does now, without all the maze of job-holders provided by his bill. If the cost is to be cheaper than now, where is the difference to be taken out? The answer is as clear as daylight. There is only one place where it can come out, and that is out of the doctor. The doctor will be systematized and mechanized to the point where he will be seeing patients as fast as they can pass through his hands, at a pittance each, under the orders of a political superintendent or inspector who can perhaps ruin his prac-

- (a) Teeth are almost wholly devoid of capacity for peripheral self-repair, which emphasizes the paramount importance of measures for the prevention of dental disorders, especially in children.
- (b) The protective enamel does not heal after removal, is not restored
- (c) The most prevalent dental disorders are usually not curable with drugs, but once under way, as a rule, can be remedied or repaired solely by medical means
- (d) All the teeth can be removed without serious effect on the functions of the jaws or the welfare of the body, so far as the removal itself is concerned, for,
- (e) unlike the many organs of vital chemical coordination, the teeth secrete nothing having any functional value elsewhere in the body
- (f) Sanitary substitutes for natural teeth, or for parts of a tooth, can be mechanically adapted esthetically for comfortable and effective maintenance of all the dental and vocal functions. The circumstances just stated (a-f) show a concurrence, in the teeth of these biological conditions (a-b) relative incapacity for repair, (c) relative incurability by medicinal treatment, (d) ready recovery from effects of total loss, (e) non participation in systemic chemical coordinations, and (f) esthetic and mechanical sufficiency of functional restorations attainable by artificial replacements. This concurrence of conditions which does not occur in any part of the body containing blood and nerves, accounts in part for the traditional unconcern among physicians regarding dental disorders, and have justified the development and maintenance of dentistry as a separate organized profession

4. The conditions just indicated (group 3) give to dental service—in its important relation to the maintenance of health and comfort, the amelioration of mechanical and functional disabilities, and to esthetic requirements—a quality that, in the interest of the patient, demands special training, understanding, and proficiency, which cannot be included either in medical education or in medical practice. Doctors of medicine who do not recognize this important fact, and who do not accord to dentists the professional credit their status and health service deserves, are seriously at fault from every consideration of medical responsibility. The patient needs oral health service, even when his dental disorders are not as serious or as urgent as some other ailments. The physician has not been educated to give the needed dental service. But the physician owes the dentist—who has not been educated for the systemic function—that degree of fraternal helpfulness which all licensed and ethical servants of the public health should cheerfully, fairly, and responsibly accord to one another. The welfare of the patient presents the paramount obligation, and points out the essential consideration, in interprofessional relationships. Let us hope that the realities of the patient's needs, the requirements of effective service in the patient's behalf, and the opportunities and responsibilities of licensed health servants to help the patient, will bring physicians and dentists together, in the patient's interest whenever either practitioner

needs the aid of the other in common effort to this end

Turning, now, from introductory generalities to the content of Dr. Magid's report I quote a statement from the Carnegie Foundation's Annual Report, for 1930, to serve as a basis for comparison of my own general findings four years ago with Dr. Magid's this year

'The accompanying summary presents an indication of the lack of concern in the medical school in the United States in 1929-30, about the 'medical part' of dentistry

Data relating to required instruction in dental relationships in United States schools of medicine in 1929-30

- 1 Number of schools in which there are no required courses of instruction in oral hygiene, clinical dentistry or oral surgery—37
- 2 Number of schools in which there are no required courses of instruction in oral hygiene, clinical dentistry or oral surgery but in which casual instruction on dental (oral) conditions is included in required courses or clinical work in other relations—29
- 3 Number of schools that give required courses or groups of lectures on various aspects of dentistry, the time allowance ranging between four and fifteen hours (average 8 hours in 4 years)—15
- 4 Total number (including the 6 proprietary schools)—81
- 5 Number of schools in Group 3 in 1924-25—a gain of 6 in 5 years—9

'If the interest in the 'medical part' of dentistry continues at its present rate of growth in the medical schools in the United States, and if the number of schools remains the same, then it may be expected that by 1985 all of the medical schools will devote an average total of eight (clock) hours in the entire curriculum to required work in dental and oral relationships"

This statement, four years ago, indicated that only fifteen medical schools in the United States, i.e., less than one in five, then gave required courses or groups of lectures on some aspects of dentistry, and that the time reserved by this small number of schools ranged between only 4 and 15 clock hours (average, 8 hours) in the entire curriculum for the M.D. Degree

The medical schools in group 3 are Boston, Cincinnati, Creighton, Detroit, Emory, Georgetown, Kansas, Marquette, Medical Evangelists', Minnesota, New York Homeopathic, Ohio State, Oregon, Temple, Washington

Before beginning a direct discussion of Dr. Magid's report, let me remind you of the fact that the use of questionnaires to elicit information is usually unsatisfactory, not only to those who issue the questionnaires but also to those who respond to them. Those who receive questionnaires commonly feel that an annoying burden has been placed upon them, usually find something particularly distasteful in referring to deficiency, feel that they are on the defensive, and think of responses that will be protective. The replies are recorded without an observer being present to check the validity, and therefore are often careless, evasive, incomplete, grandiose or otherwise misleading. The questions are often ambiguous, superficial, confusing, or inadequate to elicit pertinent information. I believe you will agree that the responses to the questions as brought out in the report made it possible for Dr. Magid to present a clear picture of realities. A more effective way for your organization to proceed if it wishes to obtain accurate information on the matters to which the questions relate would be to have a representative visit the lead-

ing institutions and ascertain, by direct inquiry and observation, just what is being accomplished and then report it to you comprehensively and judicially from the standpoint of all the facts reliably determined. I shall refer briefly and frankly, in the spirit of the preceding remarks, to the questions in Dr. Magid's report and to the responses thereto.

I. The first inquiry in the questionnaire was this: "Does the curriculum in your medical (or dental) college include theoretical or bedside teaching which aims to stress a *possible* relationship between oral and systemic diseases?" The summarized numerical returns were these:

	Report		Speakers additions	
	Yes	No	No response	Total
Medical schools.....	46	24	17	87
Dental schools.....	23	1	20	44
Total	69	25	37	131

This first question refers to "theoretical or bedside teaching," and may be truthfully answered "yes" where only either kind of instruction is given. The question ignores the extent and the quality of the instruction. Since a few incidental remarks to students, intended "to stress a *possible* relationship," etc., would enable a school to answer Yes, it is surprising to find that 24 medical schools answered No.

II. The second inquiry in the questionnaire reads: "How many years has your medical (or dental) college been giving dental (or medical) instruction?" The replies ignored the fact that the question refers directly to *number of years* during which the indicated instruction has been given, the response showing merely that there was or was not much instruction. In short, the answers were not responsive to the question but indicated something else. The summary of these miscellaneous responses, to something other than the main point in the question, were summed up as follows:

	Report		Speakers additions	
	Yes	No	No response	Total
Medical schools.....	36	34	17	87
Dental schools.....	10	11	23	44
Total	46	45	40	131

III. The third question reads: Does your college offer a combined course on medicine and dentistry? If not, have you any plan or plans to suggest for such instruction? The responses, evidently for only the first half of the question, are given as follows:

	Report		Speakers additions	
	Yes	No	No response	Total
Medical schools.....	7	63	17	87
Dental schools.....	0	22	22	44
Total	7	85	39	131

The question does not indicate what is meant by "combined course in medicine and dentistry"—whether, for example it refers to a combination of courses leading to one degree of two degrees in *undergraduate* training, or to one or more degrees in joint *graduate* work. Possibly nearly all the schools assumed that "combined course" in the question meant a combination of undergraduate medical and dental curricula leading to *both* the M.D. and D.D.S. degrees.

IV. The fourth question is this: "Does your college offer postgraduate instruction in medical and dental subjects emphasizing the relationship between the two professions in caring for the 'common' patient?" The responses were:

	Report		Speakers additions	
	Yes	No	No response	Total
Medical schools.....	12	58	17	87
Dental schools.....	9	13	22	44
Total	21	71	39	131

This question is restricted to postgraduate instruction, and places the emphasis and purpose on joint care of the "common" patient. But what is meant, in the question, by the word "common," with its quotation marks? Does the quoted word mean ordinary patient or average patient, or the patient who may need the joint ministrations of both physician and dentist, the one practitioner consulting the other? This question was probably variously interpreted, which may explain the small number of affirmative responses.

It is said, in the report, that "out of 140 questionnaires, 70 medical colleges and 25 dental colleges responded"—i.e., 95 (75 per cent) in a total of 131 such accredited colleges in Canada and the United States. I assume that the six proprietary medical colleges in the United States were not included. One statement in the report suggests that possibly nine additional copies of the questionnaire were sent to persons who did not represent colleges. Some of the most influential medical and dental schools are not represented in the replies, thus diminishing the relative significance of the outcome. In an effort of this kind, to be useful, all of the most important schools should be represented in the opinions. Unfortunately, also, each of the four questions was inadequate, both in form and import. The responses do not provide clear or definite indications of realities. The numerical summaries are mathematical in appearance only, not in fact. If the figures mean anything they suggest that the practical interest in medical schools, in imparting to medical students a working understanding of what might be called the "medical part of dentistry," is just what it was in 1930 or less. An examination, in the report, or the individual quotations from the questionnaires confirms this opinion. An element of humor for me in these replies is the fact that some of the representatives, in saying what they are about to do to correct deficiencies, stated almost verbatim what they wrote some years ago. A number of the replies contain views that, because of their general significance, ought to be emphasized. I quote a few as follows:

UNIVERSITY OF ILLINOIS: "I am writing to you because I feel . . . the questionnaire is misleading."

ST. LOUIS UNIVERSITY MEDICAL SCHOOL: "This questionnaire . . . has revived my interest in the dental internship in the University Hospital, of which we have been speaking for several years, but which has this far failed to materialize."

TULANE UNIVERSITY MEDICAL SCHOOL: "The dental instruction that is available and the dental service to patients through the dental profession (in New Orleans where there is a dental school in Loyola University) are entirely inferior to warrant more time in the curriculum (now admittedly inadequate) nor more effort to utilize dental teaching at the present time."

INDIANA UNIVERSITY DENTAL SCHOOL: "Hope to institute medical instruction in [the] dental school. Medical faculty [is] hard to convince."

UNIVERSITY OF PITTSBURGH DENTAL SCHOOL: "Dental school has offered courses in dental pathology to [the] medical, but [there has been] no acceptance [by the medical school]."

Let me assure you that, in presenting this criticism of the questionnaire and of the report, my purpose is wholly constructive. I have referred to weaknesses in order to strengthen all your future endeavors. I am anxious to help make your efforts effective.

Very recently I received, from a student of medico-dental relationships, a manuscript containing the following sentence: "The academic intercourse between the dental and medical schools (in the United States) is still in most places casual, superficial, and insincere." This conclusion agrees with the obvious facts in the situation. I urge you to face realities, and to increase your endeavors actively to stimulate further growth of co-operation between the two professions. Questionnaires regarding what is being done yield instructive responses only where constructive activity is in progress. Accord between the two professions, although growing, is like many vital processes—the reaction needs catalytic acceleration. "The Organized Medical and Dental Professions of Greater New York"—under whose auspices this convention is being held—should serve as an enzyme . . . I believe your fervent . . . the following four main . . . ro-ductive of distinguished results:

1. After due study, formulate a statement of the principles and conditions which, in your judgment, the faculties of medical and dental schools should establish to promote understanding, in medical dental students, of the responsibilities and opportunities of physicians and dentists to co-operate in behalf of the patient.

2. Forward to each medical and dental school, and to the Council on Medical Education, a copy of the statement thus formulated. With the statement send two requests: one asking for reasons, if any, why the proposed plan could not be made operative; another asking for suggestions of improvement of the plan.

3. Send, to each of the schools and councils, copies of the replies to these two requests.

4. Meanwhile, and as a closely related supplementary endeavor, compile a clear and factual statement of the efforts actually being made, and

the ensuing results in some of the leading medico-dental centers to promote knowledge and understanding, among medical and dental students, of the mutual obligations of physicians and dentists in practice and co-operation. Send copies of this compilation to each of the schools and councils. In this effort, medico-dental conditions at the following illustrative universities—as ascertained directly by you or for you—would be particularly instructive and useful, either positively or negatively: California, Chicago, Columbia, Cornell, Harvard, Johns Hopkins, Michigan, Northwestern, Oregon, Pennsylvania, Rochester, Tulane, Washington, Western Reserve, Yale.

If you directed your efforts, soon and effectively, in accordance with or in extension of the program just indicated, your committee in charge of these matters would, I believe, be able to present a very constructive report at your next annual convention, as a basis for further action. . . . You are engaged in an effort to promote a very worthy cause.

Following general discussion the Session formally adopted the following Resolution:

WHEREAS, The report indicates that there is not a uniform inclusion of medico-dental subjects in the curricula of undergraduate and postgraduate teaching in the medical and dental schools in United States and Canada, and

WHEREAS, The Joint Committee firmly believes that in the interest of public health, subjects having a medico-dental relationship should be taught in the medical and dental schools; and opportunities should be offered for postgraduate study of the relationship of Oral Diseases to Systemic Diseases, therefore, be it

Resolved, That the chairman should appoint a special committee to draft "standards" for a minimum course of study in interrelated medico-dental subjects to be taught in the medical and dental colleges in the United States and Canada, and be it further

Resolved, That when the standards are prepared, the Joint Committee shall submit them to the: (1) American Association of Medical Colleges; (2) American Association of Dental Colleges; (3) Faculties of the Medical and Dental Colleges in the United States and Canada, for their study and recommendation.

SOCIETY ACTIVITIES

(Continued from page 133)

Laboratory representatives objected particularly to the requirement of the bill that the laboratories be owned by physicians. The public health laboratories' objection was that the bill would be establishing a standard of efficiency lower than that which the State Department of Health requires at present. Associated Industries and the insurance companies directed their principal objection to the free choice clause. The proponents of the bill were the Department of Labor, organized labor, the New York Academy of Medicine, and the State Medical Society. Dr. Aranow presented the Society's approval. It is possible that slight changes will be

made in the bill before it is advanced, but there is no doubt but that it will be advanced to debate on the floor of both houses. It was suggested by the chairman of the committee of the hearing that the proposed amendments or changes be prepared immediately so that the committee can take final action on the bill not later than next Wednesday.

County Societies

Franklin County

A splendid example of the old-time general family doctor passed away in December when Dr. Watson H. Harwood, 81, a physician at Chasm Falls for nearly 55 years, died in the Alice Hyde Hospital at Malone.

Dr. Harwood, a son of Mr. and Mrs. Hiram Harwood, of North Bangor, was born in that town and was graduated from the University of Vermont Medical College. He established his practice in Glen Hope 53 years ago when the settlement was little more than a wilderness. He was instrumental in having the name changed to Chasm Falls. Most of its residents were brought into the world by the old doctor. For many years he made the breeding of fast horses and fancy poultry his chief hobby.

Kings County

The Kings County Medical Society loses one of its veteran members in the death of Dr. Henry J. Brewer, a former coroner in Brooklyn and one of the borough's oldest physicians, at the age of 88 years. He was born in this city and during the Civil War he joined the navy and saw service with the South Atlantic blockading squadron. After the war he attended the Long Island College Hospital where he received his medical degree in 1881. He retired about ten years ago after forty years of practice.

Dr. Brewer was at one time Democratic leader of the Seventh Assembly District and belonged to Winchester Post, G. A. R., Orion Lodge 717, F. and A. M., and the Medical Society of the County of Kings. His widow, Mary L. Brewer; a daughter, Elizabeth T., and two sons, Walter and William T. Brewer, survive.

On the recommendation of the Board of Superintendents a program of x-ray examinations will be begun shortly to discover incipient childhood types of tuberculosis among high school students. For the present the examinations will be limited to third and fourth-year students in Brooklyn high schools. They will be conducted by specialists under the joint auspices of the Department of Health, the Board of Education, the Kings County Medical Society and the Brooklyn Tuberculosis and Health Association, and will be similar to examinations given during the last three years to more than 15,000 elementary school children in Manhattan and Queens.

Of the 15,000 elementary school children—all seemingly well and strong—who were examined with the tuberculin test during the last three years, an average of twenty-eight in every 100 showed that they were infected with the germ of tuberculosis, it is disclosed.

Monroe County

The Monroe County Medical Society is carrying out a special plan to provide eye examinations for a group of indigent children who could not obtain attention at hospital outpatient departments. A survey reported in the *A.M.A. Journal* showed that 1,210 children were in need of refractions and that the hospitals would not be able to accommodate them for many months. The medical society in conference with the public safety and public welfare committees of the city council agreed to make the examinations for the sum of \$2,420, all to be completed by the end of 1934. Between September 15 and November 1, members of the society had completed 575 refractions. Glasses are to be furnished by the department of public welfare and various lay organizations.

Montgomery County

It may seem to some a bit incongruous to open a sewage disposal plant with dedicatory exercises, but when we think what such a plant means to a community in the way of saving health, it appears to be just about the right thing to do. At any rate, that is how they opened the new one in Canajoharie. We can understand the local feeling when we learn that for many years the village has discharged untreated sewage into Mohawk river and has maintained a public dump for disposal of its garbage and refuse. The dump especially has been the subject of many complaints in the past. The new plant was built with federal aid through the PWA. The incinerator is designed to handle twenty-one tons of garbage and refuse per day but normally will operate only about eight hours per day. Due to the large quantity of combustible material in the refuse from the village it is not expected that any auxiliary fuel will be required.

Nassau County

One of the most interesting attempts to organize the physician's time for more effective charity work is the Children's Health Hour, says the *Nassau Medical News*. Not original in this county, it has nevertheless

been given sufficient local trial to demonstrate its essential soundness as a means of solving local problems. In several Nassau County communities local physicians have established special office hours for the purpose of handling a drive to secure immunization of the children of the community against diphtheria. The local health authorities and visiting nurses have done the publicity work, which included house-to-house visiting of parents of preschool children, and the local doctors have done the immunizing in their own offices. Children able to pay full fees are handled at the usual office hours, all others are directed by the public health nurse to select a co-operating physician and go to his office at the special "Children's Health Hour" where the work will be done at a reduced fee or for no fee at all if the nurse decides the family is unable to pay.

So far this has been but a temporary arrangement and has been available in but a few communities. The profession has been able to announce, however, a similar plan to be county-wide in its extent and on a permanent basis. This particular project is the securing of eye examinations and treatments for school children. If the program is as much of a success as it has been in other communities, it is hoped that the "Children's Health Hour" may be extended to other fields of practice and to adults as well as children, thus making it unnecessary for any indigent patient either to suffer from neglect or be compelled to put up with makeshift or indifferent care. The doctors are still perfectly willing to carry the load of medical charity; they ask only two things, first that they shall be protected against the individual who seeks charity medical care when able to pay his own way, and second that they be given the help of the other interested groups to the end that the care may be given at the least practicable expense both of time and effort.

New York County

A fine tribute to Dr. Franklin Welker, the new President of the New York County Medical Society, appears in the *New York Medical Week*, which remarks that in "the controversy ranging about medical practice there is one point on which almost all are agreed. The general practitioner must be the dominant factor in medicine, the co-ordinator of all the special work required in a given case. Trained in the laboratory sciences, he must be essentially a clinician. Possessing the therapeutic skill of his great predecessors, he must be interested and adept in preventive measures. Such is the doctor of the future—and such is Dr. Franklin Welker.

"Long years in general medicine have given Dr. Welker a sympathetic insight into the

problems which the practitioner must face from day to day. He combines a deep realization of the profession's obligations to the public with a firm belief in the physician's right to professional independence and economic security. Possessed of a quiet courage that does not waste itself in bluster, he will not give ground to those who seek to exploit the doctor under the guise of various so-called reforms.

"Dr. Welker has spent many years in the service of the County Society, acting in many different posts. As president he will be aided by officers and committeemen who also are thoroughly familiar with the problems before them. Both the personnel and the experience of the 1935 administration are such as to inspire the confidence and support of the membership."

Schoharie County

It was a strange coincidence that Dr. Christopher Best, of Middleburgh, who died in December, at the age of 82, was stricken just after treating a local jeweler who was his first patient when he started practice there in 1876.

Dr. Best was active in professional organizations and civic affairs. During his life he was President of the Board of Education, director of the Middleburgh and Schoharie Railroad, President of the Middleburgh Telephone Company and Senior Elder of St. Mark's Lutheran Church of Middleburgh.

He is survived by his wife, two daughters, Mrs. E. B. Vroman and Miss Emma Best, and one son, Dr. Duncan Best, all of Middleburgh.

Suffolk County

One of the staff nurses of Suffolk County recently visited a home where the mother had given birth to a child. The nurse asked the mother if she was nursing the baby. The mother replied, no, that the doctor had ordered a new food. Asked what it was, the mother said "Wild animal's milk." The nurse, somewhat startled, asked if that was a new kind of food and what it was like. The mother said it came in a can and showed the nurse a can with the picture of a wild animal on it, a standard brand of evaporated milk.

Westchester County

A pair of office thieves have been victimizing physicians in Westchester and neighboring counties. These two worthies call on the doctor at a time when his office is devoid of patients—no unusual situation in these days—and then, while one of them is taken into the private office, the other proceeds to "get away" with everything available.

Counsel, Medical Society of the State of New York

Operation Without Consent—Surgeon's Right to Operate in Emergency

The extent to which a surgeon may act in an emergency was the subject of an interesting case* decided by the courts of one of the Middle Western States.

The plaintiff in the case was a boy, 15 years of age. While crossing a railroad track he was struck by a locomotive and severely injured. His principal injuries were to his left foot. He was promptly taken to a nearby hospital in an ambulance. Upon arrival there he was partly conscious and was able to tell his name and address to the attending surgeons. About ten minutes after admission to the hospital, however, the boy lapsed into a comatose condition, followed by complete unconsciousness. Attempts were unsuccessfully made to revive him by injections. His injuries were promptly examined by the house doctors, and he was found to be suffering from a compound disarticulation of the bones of the foot. The scaphoid bone was torn away entirely and much of the flesh was torn away from the top of the foot so that the muscles, ligaments, and bones were exposed.

After examination the house physicians concluded it was a case for immediate surgical procedure and they notified the defendant, an experienced surgeon, who came to the hospital without delay. The defendant found the boy unconscious, with a poor pulse. He found the injured foot to be apparently cold and dead, with its circulation interrupted. The defendant inquired as to the whereabouts of his parents or other relatives of the boy, and was told that none were available. He thereupon held a consultation with the four house physicians who had examined the patient, and it was agreed that immediate amputation of the foot was necessary to save the boy's life. The operation was performed without further delay by the defendant. The patient had an uneventful recovery.

Sometime later an action for damages were begun against the surgeon upon the theory that under the circumstances, it

was not proper for the surgeon to amputate the foot. The claim was made that it was unsound medical practice for the defendant to amputate the foot at all, and that in no event should it have been amputated without first obtaining the consent of the patient or his parents.

Upon the trial of the action the plaintiff called three medical witnesses on his behalf, all men of considerable experience and they gave testimony upon their direct examination that, having examined the foot after it had been amputated, it was their opinion that the foot could have and should have been saved. The force of their testimony was broken down upon cross-examination, as will be seen from a few passages from the testimony so elicited from them by the defendant's attorney.

The first of the said experts gave the following testimony:

Q. Suppose the injury was so severe that the circulation had ceased, would you clean the wound and leave it? A. If the bone were all crushed and the parts all torn, and I saw no chance, I would amputate.

Q. Would you form your own opinion and judge whether amputation was necessary or not? A. I would call in counsel. I would not rely upon my own judgment. I would talk it over. Other people might see things differently than I did. Surgeons have differences of opinion. With proper consultation, it is a question which is the best course to follow under certain circumstances. I would call at least one surgeon, and if I was not satisfied with his statement, I would call another. We would talk it over and consider it.

Q. Would you take their judgment? A. Certainly we would talk it over and consider it. We are often in doubt in medicine. * * *

Q. A surgeon must determine, must he not, when an amputation shall be performed, and form his judgment from all the circumstances of the case. A. I will answer that, "yes." After he takes all the facts into consideration, then he may be wrong in his judgment.

Q. And it is up to him therefore to determine from what he can learn of the case, and what he can see of the injury, to what

* *Luka vs. Lowre*, 136 N. W. 1106.

extent the danger of blood poisoning is imminent. A. Yes, sir.

Another physician called by the plaintiff gave the following upon his cross-examination:

Q. Assuming that the man was a competent surgeon and he was called in to attend this case, he would have to rely upon his best judgment? A. Yes, sir.

Q. Taking everything into consideration. A. Yes, sir. * * *

Q. You would have a good deal more faith in your own opinion if you had attended the boy at the time? A. Yes, sir.

Q. You would have a good deal more faith in some other competent surgeon's opinion that had attended the boy at the time? A. Than what?

Q. Than your own now? A. Of course, a competent surgeon attending it.

Q. His opinion would be better than yours? A. Yes, I think it would.

A third doctor called as an expert by the plaintiff, in the course of his cross-examination, gave the following testimony:

Q. If as a skilled surgeon you had seen the patient, seen the foot torn and open, and observed his condition, his pulse and all that, and you concluded that the operation was immediately necessary, would you feel that your opinion was better and more apt to be correct than that of a surgeon or doctor who saw the foot after the amputation had taken place. A. That can be answered in this way: That a man that made all those examinations and saw it, he might not be as competent after that to judge as some one else who had more experience and had seen these things oftener, and yet he might be absolutely correct, but his chances would be superior, undoubtedly, to the man who did not see it. Still, although the foot afterwards might not indicate the necessity for amputation, yet the necessity may have existed.

Q. A surgeon who saw it afterwards would not know anything about it afterwards, whether it was necessary or not? A. He would not know whether it was necessary for amputation so far as that is concerned, but the question would be whether an immediate operation would be necessary; that would be the question. * * *

Upon the trial the proof was contradicted to the effect that the circulation of the patient's foot was completely interrupted before the operation, that he was in a profound coma, and that death from shock frequently follows severe traumatic injury. The defendant's contention that immediate amputation was necessary to save the boy's life was borne out by the testi-

mony of two surgeons of wide experience, called by him as experts.

The plaintiff upon the trial failed to present any testimony to establish that if the parents had been present at the hospital before the operation was performed they would have refused their consent to the operation.

With the testimony in such shape before the trial judge, he, at the conclusion of all the evidence, directed a verdict in favor of the defendant thereby ruling there was no question to be submitted to the consideration of the jury. An appeal was taken bringing up the case for review before the highest court of the State, and the final determination of the litigation was an affirmation of the judgment in favor of the doctor.

The Appellate Court carefully considered the testimony on behalf of the plaintiff, and appraised it as amounting to no more than the opinion that if another course had been followed possibly the foot might have been saved, and that in such cases as the one before the Court, the duty of the surgeon was to first seek consultation and then to use his best judgment and go ahead. According to the Court the defendant had measured up to the standard set by plaintiff's experts, having consulted with the four house surgeons, and then in his best judgment, having undertaken the operation as an emergency measure to save the patient's life.

The Court ruled that there was no question under the facts of the case that a true emergency existed, and summarized the law as applied to the situation as follows:

It would be unreasonable to hold a properly qualified physician or surgeon responsible for an honest error of judgment, where, as in the instant case, he is called upon to act in an emergency and must choose between two courses of action either one of which involves the possibility of the gravest hazard to the patient.

It is, we think, very clear upon this record, that the question presented to the defendant, at the moment he was called upon to act, was one of judgment only. Instant action of some sort was imperative. In reaching a conclusion as to the proper course to be pursued, the attending surgeon must necessarily be influenced by many considerations: The physical character of the wound, the fact that there was a compound dislocation of the bones of the foot, the entire absence of one of these bones, the stripping off of the flesh from the anterior part of the foot, leaving the tendons

bare and shiny, the fact that the foot had become wholly devitalized, the presence of hemorrhage, the danger from blood poisoning at the time, or from future infection, the character and quantity of foreign matter, dirt, cinders, and so on, in the wound.

To a consideration of these matters must be added a careful attention to the general condition of the patient, the degree and cause of the existing shock, the apparent ability or inability of the patient to resist shock, the condition of the temperature, pulse, and respiration, and the reaction or lack of it produced by the administration of stimulants.

Called upon to act under such circumstances and to determine which of two courses (one entailing certain mutilation and the other probably death to the patient) should be followed, it is apparent that the defendant is not bound by the ordinary rules of negligence, but is entitled to insist that, having used his best judgment, he is not liable.

The Court also said in its opinion:

The fact that surgeons are called upon daily, in our large cities, to operate instantly in emergency cases in order that life may be preserved, should be considered. Many small children are injured upon the streets in large cities. To hold that a surgeon must wait until perhaps he may be able to secure the consent of the parents before giving to the injured one the benefit of his skill and learning, to the end that life may be preserved, would, we believe, result in the loss of many lives which might otherwise be saved.

It is not to be presumed that competent surgeons will wantonly operate, nor that they will fail to obtain the consent of parents to operations where such consent may be reasonably obtained in view of the exigency. Their work, however, is highly humane and very largely charitable in character, and no rule should be announced which would tend in the slightest degree to deprive sufferers of the benefit of their services.

BLOOD TESTS IN PATERNITY CASES

When an unwed mother in Sweden accuses a man of being the father of her child, he can demand a blood test to show his innocence. In this country the courts have been reluctant to admit such evidence, but both the medical and the legal professions view the possibility of it with interest.

It is said by a writer in the *Ohio Bar* that in a high percentage of illegitimacy cases an innocent man is wrongly accused, and a blood test can clear him, it would serve the ends of justice. As many know, human blood has been classified in four groups, depending upon the presence or absence of certain chemical substances, which accounts for the four possible combinations, gives the blood certain characteristics which remain constant, and which are transmitted from parent to off-spring in accordance with the well-established Mendelian law of heredity.

On the basis of this knowledge, blood tests of the mother, the child, and the alleged father reveal in a certain percentage of cases that the man could not possibly be the father of the particular child. The only method by which one of these substances can be present in the blood of the off-spring is by inheritance from one of the parents. Consequently if the blood of the mother does not contain a substance found in that of the child, one whose blood did not contain that particular substance could not be the father of that particular child.

In cases other than those in which the test establishes the fact of non-paternity, the result of the test is not conclusive—no more defi-

nite conclusion being possible than that the man might be the father of the child. The number of cases by which it is possible to establish non-paternity by this method has been estimated to be about one-third of the total number of cases tested.

Dr. L. H. Snyder, Professor of Medical Genetics of the Ohio State University College of Medicine, is developing other tests which it is anticipated will enable the fact of non-paternity to be established in a very high percentage of cases. Three Ohio courts have decided favorably on requests for blood tests in paternity suits, while two courts, one in South Dakota and one in New York State, have ruled adversely. In this state, as related in the *Ohio Bar*, the New York Supreme Court in the case of *Beuschel vs. Manowitz* (151 Misc., 899, 271 N.Y.S., 277 [1934]) held that an order at the request of defendant subjecting plaintiff and her child to blood group tests should be granted; but this decision was reversed by the Appellate Division (272 N.Y.S., 165 [1934]).

A manufacturer's bulletin remarks that "it is ill-advised economy to prescribe or dispense on a price basis even though cheaper labels may read the same as higher priced ones. Cheap drugs are expensive drugs in the long run. Added pennies may be worth as many dollars in satisfaction. They may be represented in the selection of materials, in scientific supervision, skilled production methods, standardization, clinical background, or any one or more of a dozen means of adding value to a product."

An Atlas of the Commoner Skin Diseases—By Henry C. G. Semon. Baltimore, William Wood & Company, 1934. Quarto of 221 pages, illustrated. Cloth, \$12.00.

BOOKS REVIEWED

International Clinics—A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 2, 44th Series, 1934. Louis Hamman, M.D., Editor. Octavo of 317 pages, illustrated. Philadelphia, J. B. Lippincott Company [c 1934]. Cloth, \$3.00.

The first article by Longcope gives an account of two patients who suffered from excessive edema associated with abnormally low plasma proteins due to protein deprivation, in these patients associated with disease of the digestive tract, etc. A review of the pathology follows this.

... .. surgery than on medicine

... .. "Operative Shock,"

... .. "Exophthalmic Goitre,"

... .. in the Treatment of Pulmonary Tuberculosis, and two on "Peptic Ulcer"

Recent progress in obstetrics and pediatrics includes a review of the toxemias of later pregnancy and of immunization against diphtheria and scarlet fever.

W. E. McCOLLUM

Organic and Bio-Chemistry By R. H. A. Plimmer, D.Sc. Fifth Edition. Octavo of 624 pages, illustrated. New York, Longmans, Green & Company, 1933. Cloth, \$7.50.

Recently a considerable amount of organic chemistry,

formerly omitted from texts of this nature, has suddenly become of vital importance in physiological and biological inquiry. It is a Herculean task for the average student in medicine, biology, or chemistry to keep abreast of the times and informed of current advances in his chosen field by perusal of the countless number of texts and articles. It is not likely that he would be qualified to cull the wheat from the chaff—to differentiate between purely experimental interest and fundamental knowledge. This substantially is what Professor Plimmer has done in this book.

The book is consequently an extension and amplification of a previous edition. The subject matter has been thoroughly revised and brought up to date, the new mass of material making an appreciable change in the subjects both theoretical and practical. Viewed from the practical, only the vital reactions and evidences of organic substances and processes are stressed, controversial aspects being omitted. From the theoretical standpoint, the subject matter is always in accordance with the method or procedure being discussed, the author correlating the material as much as possible with medical investigation.

Space will not permit a full discussion of all the interesting aspects of this book, but the student will find the text more than adequate for his needs.

SAMUEL G. DUBOFF

Medical State Board Examinations.—Topical Summaries and Answers.—By Harold Rypins, M.D. Octavo of 448 pages. Philadelphia, J. B. Lippincott Company, [c. 1933] Cloth, \$4.50.

The medical student in taking his final examinations after four years of constant application to his studies is usually under severe mental strain and not always in the best of physical condition. The State Board Examinations mark the final barrier which he must overcome before he is admitted to the practice of medicine. In presenting the book on Medical State Board Examinations, Dr. Rypins shows that he has taken these facts into consideration, since it is apparent that he understands the psychology of the medical student.

The personal foreword to the candidate for examination contains splendid advice which if followed by the candidate will help him in overcoming that panic which as stated by Dr. Rypins "is not an uncommon cause of failure."

The book itself contains ten chapters covering all phases of medicine including anatomy, physiology, chemistry, bacteriology, pathology, hygiene and preventive medicine, obstetrics, gynecology, medicine, and surgery. The subject matter in each section is very briefly and intelligently discussed. These discussions are followed by questions taken from the various State Board Examinations. A perusal of these questions shows that if the student has been diligent in his studies he should be well qualified to pass the examination.

The detailed index will be found very useful for easy reference.

The book is recommended to all students preparing for State Board or other licensing examinations.

REUBEN FINKELSTEIN

America Self-Contained.—By Samuel Crowther. Octavo of 340 pages. Garden City, N. Y., Doubleday, Doran & Company, 1933.

Here is a treatise on those economic and political problems which have to do with the international dependence of the United States of America—or, rather, had to do with them. For, as the author shows America is now, and can continue to be, self contained because of the scientific development at home of those products which once we were compelled to obtain elsewhere.

Credit for the evolution of this self-sufficiency is given to those scientists who met the demands made by the exigencies of the World War in the manufacture of drugs and chemicals. This work was encouraged and directed by the activities of the Chemical Foundation, created by President Woodrow Wilson. The author shows how the chemical industry in this country was all but throttled by unfair competition on the part of its German competitors.

Many other problems in addition to the development of the chemical industries are discussed; such as the political and economic significance of the international debts, free trade and the tariffs, and foreign entanglements. To those interested in the story of the economic development of the United States, *America Self-Contained* offers enlightening and instructive reading.

JOSEPH RAPHAEL

Surgery of a General Practice.—By Arthur E. Hertzler, M.D., and Victor E. Chesky, M.D. Octavo of 602 pages, illustrated. St. Louis, C. V. Mosby Company, 1934. Cloth, \$10.00.

This volume is an enlarged edition based upon the last edition of *Minor Surgery* which appeared in 1930. The authors have endeavored to present the general practitioner with as complete a number of minor surgical procedures as can be readily handled in the doctor's office.

The pathology and the various steps of the surgical treatment are in most instances clearly illustrated. The number of those published in the 1930 edition of illustrations, partly and include many new fully lesions.

The subject covered and the book should prove of general practitioner who has had some and is qualified to apply that and

Curtis' text-bo
free from acad

It is clear,
truly

of the author's well-known conservative viewpoint. As one would expect the chapters on gonorrheal disease of the female genitalia and the cellulitis group of pelvic infections are particularly good. It is interesting to note that the author recommends for prolapse an advancement operation which he describes as similar to the Manchester or Fothergill operation. In the management of ruptured ectopic pregnancy, Curtis delays operation when the patient is in profound shock, and does not intervene in those cases where symptoms have subsided, until reaction has taken place or there is failure of improvement. This is perhaps not generally accepted teaching, but proper practice in the opinion of Brooklyn gynecologists. A fine text-book for students, and one that many specialists will find stimulating.

CHARLES A. GORDON

Clinical Toxicology.—Modern Methods in the Diagnosis and Treatment of Poisoning. By Erich Leschke. Translated by C. P. Stewart, Ph.D., and O. Dorrer, Ph.D. 12mo. of 346 pages. Baltimore, William Wood & Company, 1934. Cloth, \$5.00. (The Gloucester Series.)

To confine the subject of toxicology in a small volume that will be of assistance to the physician is no easy task. In the English translation of Prof. Erich Leschke's *Clinical Toxicology*, the reader will find a small book that meets this requirement. The author states in the preface that, "it does not claim to compete with the existing excellent toxicological and pharmacological works, but should rather stimulate their closer study."

The subject is presented from the clinician's point of view, containing case histories, treatment, analytical methods, some illustrations, and a well-arranged index. The translators have added a chapter by Dr. Koelsch, who is connected with the medical inspection of factories in Bavaria. While the subject is presented along the lines of German medical practice, it will be of aid to the physician interested in compensation service in the United States.

The book is well arranged with a short introduction. Part I comprises "Poisoning by Inorganic Substances," while Part II is devoted to "Poisoning by Organic Substances." There are three appendices covering "Industrial Poisoning," "Post-Mortem Detection of Poisoning," and a list of drugs under their trade names.

While the book may appear rather abridged in some subjects, it is just such a volume as the physician needs at hand to assist him in arriving at a correct diagnosis. The volume should prove of value to the physician engaged in industrial medicine, as well as to the general practitioner, and is recommended as an addition to the physician's reference library.

C. T. GRAHAM-ROGERS

Nephritis and Allied Diseases.—Their Pathogeny and Treatment. By Robert Platt, M.D. Octavo of 166 pages. New York, Oxford University Press, 1934.

In the preface the purpose of this work is clearly stated "to present what the author has found of most practical value in our knowledge of Bright's disease at the present day." A review of the book shows that he has accomplished his purpose. To the American student it seems regrettable that more emphasis has not been laid on the work of Addis and Oliver, particularly their method of counts of the concentrated urinary sediment. Dr. Platt adheres to the simpler classification of nephritis and rightly so and shows by his diagram that they all lead to renal failure.

In treatment he belongs to the group who believe that high-protein diets favor the development of nephritis. He prescribes low-protein diets in acute, subacute, and chronic nephritis, not because of the proteinuria but in order to minimize the work of the kidney in excreting nitrogenous products. His diets contain absolutely no protein except that derived from milk, fruit, and vegetables.

In the diagnosis of uremia the author mentions the blood indican as a simple and valuable test as it is always found to be high in true uremia. The reviewer is not familiar with the use of this test.

When discussing drug therapy he emphasizes the point that no drug has a specific effect upon the kidney. There is value in repeating this fact. He warns against the use of salyrgan in the edema of nephrosis and says that it can be used only after all other methods have failed and extensive edema has remained stationary for a long time. Urea and ammonium are good diuretics.

The reader will find this work an excellent orthodoxy of present day knowledge of nephritis.

EDWIN P. MAYNARD, JR.

THE ACTION OF THE AUTONOMIC NERVOUS SYSTEM AS
AN EXPLANATION FOR THE THERAPEUTIC VALUE
OF THE CARBONIC ACID BATHS IN
DEGENERATIVE CARDIAC DISEASE

ALEXANDER LAMBERT, M.D.

*Consulting Physician to Bellevue Hospital
Emeritus Professor of Clinical Medicine, Cornell Medical College
New York City*

For centuries the use of baths has been a wide spread method of medical therapeutics. The development has been largely empirical and since Beneke, Groedel, and Schott a generation ago began to use the waters at Nauheim for specific cardiac therapeutics the empirical knowledge has increased greatly in wisdom and skill. But no accurate explanation could be given for the therapeutic effect of the CO₂ mineral baths over the plain water baths of the same temperature. Even the increased knowledge of heart disease and the increased skill in the clinical examinations and the results from the tests of gas metabolism have brought no corresponding explanation for the therapeutic effect of the carbonic acid bath.

What becomes of the CO₂ gas after absorption through the skin and what are the essential effects in the body beyond its cutaneous action were the mooted questions which remained unanswered. Although the undeniable benefit derived by the patient in certain degenerative diseases of the heart was increasingly evident, the cardiac mechanism through which these CO₂ baths produced the beneficial result was not evident and remained unexplained.

After many years of investigating by every available method of approach those most experienced in the application of these CO₂ baths have become convinced that it is through the mechanism of the autonomic nervous system that the resulting beneficial changes in the body take place. Recently Loewi¹² and Cannon^{2, 3} have each brought forward conclusive evidence that the action

of the autonomic nervous system is produced by the humoral secretion of chemical substances which mimic the action of local nervous stimulation, and yet may be transported by the blood stream and produce their characteristic effects in distant areas of the body. The acceptance of these new facts requires such a change of view point that it seems necessary before discussing the action of the CO₂ baths, to describe rather fully some of the physiology of the autonomic nervous system.

PHYSIOLOGY OF THE AUTONOMIC SYSTEM

Until the delicate balance of our circulation has broken down, few persons realize how every movement, every strong emotion, every change in external temperature, requires some accommodation of the nervous balance of the autonomic nervous system to produce the required energy, and to bring the nervous mechanism back into its usual normal equilibrium. Cannon¹ calls it the production of "homeostasis of the body," which implies the likeness to stability produced by the interplay between the opposing functions of the sympathetic systems. In the reactions between the two portions of the autonomic system, any discharge of sympathetic energy is sent throughout its entire system, while a discharge from the parasympathetic or vagal system is sent to the separate nervous ganglions situated in, or near, the organ requiring individual action.

Thus the pupil may be contracted by the vagus, without slowing the heart, or the heart slowed without affecting the increased

motor action of the stomach. On the other hand, an emotion, like rage, causes a general sympathetic discharge, producing certain set actions throughout the body, simultaneously affecting the circulatory, cardiac, pulmonary, and splanchnic areas.

In ordinary, quiet existence the balance between the parasympathetic and sympathetic portions of the autonomic nervous system is kept in equilibrium by the predominant function of the sympathetic system in some portions, and in other portions by predominant function of the parasympathetic. The equilibrium of the autonomic system⁴ is not one of quiescence, it is one of active stimulating tone; in general the sympathetic accelerates the heart, contracts the arterial and venous vessels, stimulates the adrenalin secretion, increases the respiratory activity, dilates the pupil, increases thyroid secretion, diminishes the gastro-intestinal peristalsis, activates the discharge of glycogen from the liver, contracts the spleen to pour out increased red blood cells for increased supply of oxygen, and increases the general metabolism. With opposing function the parasympathetic inhibits the heart, dilates the blood vessels, inhibits the adrenalin secretion, diminishes respiratory activity, contracts the pupil, inhibits the thyroid secretion, increases the gastro-intestinal peristalsis, and checks the discharge of glycogen from the liver and diminishes the general metabolism.

The main element which interests us here in the autonomic balance is that the heart lies normally under the dominating control of the parasympathetic. The blood vessels, on the other hand, normally rest under the active tone of contraction by the sympathetic system. There is therefore the same antagonistic control between the two parts of the autonomic system in its balance within the heart and between the heart and vascular circulation, that there is in the balance of the varying opening and closing of the sphincters in the intestinal canal. The delicate balance is preserved because of reflex action of opposing function.

In healthy youth, the heart can stand the strain of any exertion, and it can also retain its vigor through long years of life. But as years go on the heart becomes degenerated by many attacks of sickness, or by years of inertia, and dietary excesses, it becomes out of condition, it then

on exertion is unable to supply sufficient oxygen to the tissues, and will produce the shortness of breath, which halts its struggling owner. Or if from failure of sympathetic reflexes there is lack of blood sugar to supply the required energy, there will arise an early excessive exhaustion, which forces cessation of action, however much the indomitable will of the personality may struggle against it. Emotions of fear, or worry, which is fear, and sorrow, pain and anger play a greater part in the wear and tear of life than do work or exertion, and cause intense reactions in the autonomic nervous system.

It is unnecessary to go into explanatory details, but the three seemingly disconnected happenings in the body, of exertion, emotion, or sudden entrance into a cold environment demand increased cardiac output, and often bring on attacks of angina pectoris. The degenerated heart cannot perform the necessary redistribution of the blood over the body without supplying this immediate demand for the increased output per beat, which in its degenerated condition is an excessive demand. Pain results and acts as a warning signal that excessive demands have been made on the heart, which require relief or instant cessation. Pain is a pathologic not a physiologic reaction.

It is immaterial for our present purpose to discuss the reasons of the pain, since the medical theories of the causation of cardiac pain are still under discussion.

Variations in blood pressure have long been known to be a large factor in the balance of the circulatory equilibrium, but the controlling mechanism of the blood pressure has not until recently been worked out.

The work of Hering⁴ and Heymans, Bouckaert, and Regniers⁵ on the two aortic depressor and the two carotid sinus nerves, has revolutionized the conception of the mechanism which controls the blood pressure, and shows that these four nerves are a dominating factor in the balance between the heart and the peripheral circulation. They are justly called by Hering⁴ the vagal reflex restrainers of the blood pressure.

For many years it has been recognized that the aortic depressor nerve, distributed over the aorta, and the bases of the innominate and left subclavian arteries, was an afferent nerve, having its ganglionic

cells in the ganglion nodosum of the vagus. There is distinct evidence that these ganglionic elements of the aortic depressor nerves are connected with the centers in the medulla by fibers, which follow the lower bundle of the glossopharyngeal nerves. This is particularly interesting as the carotid sinus nerves, as we shall see, are also branches of the glossopharyngeal, acting as part of the parasympathetic system.

The work of Hering⁴ and especially the anatomical work of de Castro⁵ emphasize that where the common carotid artery divides into the internal and external carotids, there is an enlargement of the internal carotid, which is not aneurysmal, nor accidental, but is a normal peculiarity for men, and most mammals.

In cattle, however, this sinus occurs on the occipital artery, because in the bovine animals the common carotid divides into three vessels an occipital artery, a glossofacial and the external carotid, there being no internal carotid artery.

The carotid plexus of nerves is formed by branches from the ganglion nodosum of the vagus, and a branch from the superior sympathetic ganglion, but the main nerve supply arises from the glossopharyngeal as a single nerve, just as this last nerve leaves the jugular foramen, or comes by several nerves from the pharyngeal branches of the glossopharyngeal. All these nerves spread out abundantly in the adventitia of the internal carotid as this vessel enlarges to form the carotid sinus and they also supply the important carotid glomerulus resting in the bifurcation between the internal and external carotid arteries. This small, round, so-called carotid gland or glomerulus, occurring normally at this point, is not an endocrine gland, it has no secretory action in its cellular lining, but is richly supplied with blood vessels from the carotid artery and its cellular structure is abundantly furnished with nerve fibers, whose endings are not of a secretory type, but are those belonging to an efferent nerve. De Castro's⁵ conclusions are that this carotid glomerulus is a sensory organ, probably especially designed to respond to certain qualitative modifications in the blood. In fact, Heymans and his co-workers produce strong evidence that these conclusions are

justified,⁶ since they have shown that the nerves sensitive to variations of pressure are situated in the walls of the carotid sinus while the nerves sensitive to chemical excitants are confined to the glomerulus.

Variations in the CO₂ tension,⁷ and doses of nicotine or lobulin so small as to be inert when injected through a denervated carotid sinus, effect intensely the respiratory and circulatory centers of the medulla through nervous reflexes originating in the innervated carotid glomerulus. Although the respiratory and other centers are highly sensitive to changes of the blood pressure, through reflexes coming from the nerves of the carotid sinus, these centers are relatively insensitive to variations of pressure in the large vessels going directly to the medulla. The respiratory center is also more sensitive to reflexes due to changes of blood pressure in the carotid sinus and aortic zones than it is to variations in the chemical composition of the blood.

Heymans⁸ and his co-workers conclude that the CO₂ seems to be the primordial stimulant to the sympathetic system, raising the arterial blood pressure. The reaction of the parasympathetic results from this endovascular blood pressure causing the reflexes from its carotid sinus and aortic depressor nerves to reduce this rising pressure, thus in turn producing and preserving the normal autonomic nervous balance.

Whether or not the balance between the sympathetic and parasympathetic portions of the autonomic nervous system is so completely dependent on the carbonic acid on the one hand, and on the variations of pressure tone on the other, remains to be decided in the future, other chemical substances, at present unrecognized, may well enter into the rise and fall of the blood pressure.

Loewi¹² and Cannon¹³ have recently brought forward evidence which shows that the autonomic nerve impulses become effective through chemical substances secreted by the nerve endings themselves. The nerve endings of the autonomic system to smooth muscles and to the myocardium are distributed in a network around the nucleus of the muscle cell. But only one nerve supplies a cell. There seems to be no accurate histological evidence that a single cell is supplied by both a sympathetic and parasympathetic nerve,

but there is strong histological evidence to show that not more than one cell in a hundred is connected directly with the autonomic nervous system. The humoral chemical substances distributed over these cells supply the actions which mimic the reaction from the sympathetic or parasympathetic nervous stimulation.

Loewi¹² in 1921 showed that the vagus, when stimulated directly in an isolated frog's heart, produced a substance which in turn gave the characteristic vagal cardiac inhibition when transferred to a second isolated heart deprived of its vagus. This was designated "vagus substance" which later Loewi showed to be identical with acetylcholin and is now generally so accepted. Atropin was shown to inhibit vagal action through prevention of the action of acetylcholin in the responsive cell mechanism, but atropin does not paralyze the vagal nerve endings. Further, the increase of vagus stimulation by eserine (Physostigmin) was not due to any effect on the vagus itself but due to the prevention of destruction of the acetylcholin by a heart muscle esterase. Acetylcholin is a labile substance, dialyzable, but quickly destroyed in blood or tissue esterase and in an alkaline medium, but preserved by all free acids. The esterase action is diminished by increase of CO₂ tension, that is by increased hydrogen concentration. Not only has it been demonstrated that the cardiac vagus secretes this substance, but it has also been proven for the lingual, chorda tympani, and oculomotor nerves and for the parasympathetic nerves of the stomach, and also for the peripheral vasodilator nerves. Cannon suggests the name of parasympathin for Loewi's vagus substance.

Cannon^{2, 3} and his co-workers have also brought forward conclusive evidence that a sympathetic substance is released from stimulated cells under physiological conditions, and they have proved that "the heart, the salivary glands and nictitating membrane, deprived of sympathetic innervation, exhibit responses characteristic of sympathetic influence when smooth muscle of remote regions is stimulated by way of sympathetic nerves and when the only communication is through the bloodstream. The evidence seems quite clear that not only are the sympathetic mimetic and parasympatheticomimetic substances produced when smooth or cardiac muscle is stimu-

lated by corresponding nerves, but that these substances diffuse out from the affected organs into the circulating blood and under appropriate conditions can have typical mimetic effects on distant organs." This substance thus secreted is called sympathin and resembles adrenin. Both these substances cause, when carried by the bloodstream, acceleration of the heart, rise of blood pressure, contracture of nictitating membrane, and so on. But after the injection of ergotoxine material differences of action are shown by adrenin and sympathin, they are therefore different. There are two kinds of sympathin; sympathin E, given off from smooth muscle which is excited to contract by sympathetic impulses and sympathin I from smooth muscles excited to relax. Both forms of sympathin, escaping from their cells of origin, may be carried by the bloodstream and are capable of causing contraction or relaxation in distant smooth muscle organs which respond to sympathetic influence.

After the injection of ergotoxine, however, there is just as much sympathin E formed as before, but the ergotoxine combines with the sympathin E and prevents its action on the responsive mechanism of the contracting muscle. Ergotoxine, like atropin, does not act on the nerve fibers.

It has been known for many years that pressure on the carotid artery at the level of the upper edge of the larynx, below the angle of the jaw, produced a temporary slowing of the heart in many people, while in others there was no effect.

In recent years, since blood pressure could be measured, it has also been recognized that with this cardiac inhibition, there was also a fall of pressure, which often occurred, even when cardiac reflexes did not take place, and persisted longer than the temporary inhibitory effect on the heart. This has usually been known as Tschermak's test, and was believed to be due to pressure on the vagus nerve. Hering, however, has shown definitely that it is not a response of the vagus, but is due to pressure on the carotid sinus. Pressure on the vagus does not produce either the cardiac, or blood pressure reflexes, nor does pressure on any part of the carotid artery, except on the area of the sinus, produce change of blood pressure or cardiac inhibition.

In persons with healthy, normal circulations there is, as a rule, a distinct, but slight

response to this test. Among those, however, suffering from arteriosclerosis, or with hypertension, the response is much more frequent, and often very marked, and in a certain number, the response is even severe, producing cardiac arrest, convulsive seizures, and unconsciousness for a short period.

It is evident therefore that hearts degenerated by arteriosclerosis are more than normally sensitive to nervous reflexes of the autonomic nervous system, and they may respond with an intense reaction to even slight stimulation. As the myocardium degenerates the heart is therefore increasingly responsive to its nervous mechanism. This clinical evidence is of value in the explanation of the therapeutic effects of baths in cardiac therapeutics.

PHYSIOLOGY OF THE CO₂ BATHS

The weight of evidence at Nauheim⁵ and Saratoga Springs seems to indicate that for the average cardiac patient, the most beneficial bath is that of the half- or three quarter bath, at a temperature of about 34°C. (93.2°F), in which the thermic effect of the bath is at a minimum, and in which the exposure of the body to the absorption of the gas is also moderately extensive, the bath being of short duration of ten minutes, or less, continued for a certain number of days, usually about eighteen or twenty baths. This seems to give the best physiologic effect of the carbonic acid in the body, and the most invigorating action on the cardiac mechanism. For the present purpose it is unnecessary to discuss the variation in the baths themselves, or the variability of the indications for their use.

The difference between the carbonic acid baths and other mineral baths is essentially due to the content of carbonic acid dissolved in the water. In these baths carbonic acid clings to the skin, in the artificial CO₂ bath in large bubbles, and in the natural baths in small bubbles, the gas in these bubbles is not absorbed by the skin, it is the areas of skin between bubbles which are the intake points of the CO₂ into and through the skin, it is the CO₂ dissolved in the water which is the effective agent. For this reason, the waters naturally containing the dissolved carbonic acid apparently are more efficient, than those in which the carbonic acid has been artificially produced. There is a sense of warmth pro-

duced in the skin by the action of the CO₂. This and the reddening of the skin occurs whether or not the bubbles are left on the skin, or are continuously gently rubbed off every few minutes.

The carbonic acid causes a marked reddening of the skin as far up on the body as the water extends on the submerged skin, the redness stopping sharply on the line where the skin ceased to be wet by the carbonic acid water. It is therefore not a reflex action, but a direct action of the CO₂.⁶ Krogh⁶ has shown that increased CO₂ tension in the tissues greatly dilates the capillaries and arteries. If the arm be held against the axilla under the water during the bath, the area of the contact will remain glistening white, sharply marked off from the reddened skin around it.

Although the air above the CO₂ bath contains a varying proportion of carbonic acid gas, usually below 5 per cent, this CO₂ varies according to the temperature of the bath, the amount of CO₂ in the water, and the movements of the top layer of water and the air above it. This CO₂ can readily be, and often is, absorbed by the lungs in respiration during the bath. This is especially true of the full bath. In the three quarter, and the half bath, the face of the patient is too high above the water to have the gas mix with the air to any noticeable effect. There is evidence that the CO₂ thus absorbed does not seem to produce any increased cardiac effect. Groedel,⁷ moreover states that the respiration is noticeably deepened and respiratory volume increased almost immediately in the half and three quarter baths as well as in the full baths, even when the patient is protected against breathing any CO₂ gas. This was also true in the careful experiments of Groedel and Wachter⁸ on the gas metabolism of these CO₂ baths.

These experiments clearly show that with the CO₂ Sprudell bath water at 33°C. (91.4°F) of ten minutes' duration, the oxygen consumption rose about 8 per cent, while the CO₂ output increased to between 24 per cent and 34 per cent. The respiratory volume followed the carbonic acid curve, and although the depth of the respiration and respiratory volume greatly increased, the respiratory frequency did not increase or varied but little. After such a CO₂ bath, the oxygen demand returns to normal in about eighty minutes, the car-

bonic acid excretion, however, after 100 to 200 minutes may not yet be fallen to the original figure present at the beginning of the bath.

In striking contrast to these results is the gas metabolism in the plain water baths of indifferent temperature between 34°C. to 36°C. The oxygen consumption rose to between 5 to 8 per cent. The carbonic acid production rose in half of the cases to between 1 to 5 per cent; in the other half it was negative. The respiratory quotient in consequence always sank below the original value. The continuation of these baths produced, in general, the same results.

Of course, the mooted questions in these CO₂ baths was the origin and effect in the body of the CO₂. Hediger¹⁸ has finally proved the actual absorption of the CO₂ by the skin, and that it depends on the laws of diffusion through membranes and on the concentration of the CO₂ in the penetrating fluid. In the natural baths at St. Moritz, or Nauheim, this absorption rate was calculated to amount to about 200 c.c. a minute. Harpuder,⁹ in his extensive review on these baths, concludes that the CO₂ diffusion through the skin is evidently so well compensated by the respiration that measurable changes of the alkali reserve or of the pH do not occur.

This conclusion is based chiefly on the work of Liljestrand and Magnus,¹⁷ who found that the oxygen did not increase but the increase of CO₂ was so entirely controlled by the hyper-ventilation of the lungs that there was a fall in both the venous and arterial CO₂ tension, as shown by the alveolar CO₂. Of course, the alveolar CO₂ tension is equivalent to the CO₂ tension of the arterial blood. The respiratory quotient rose, in some experiments even to 1. There was an increase of respiratory volume, but the respiratory frequency did not change in one subject, while in the other it increased only on the average of four from 8.8 to 11 per minute.

These investigators deny any effect in the baths to the CO₂ or its absorption by the skin. They accept the skin irritation from the CO₂ to explain the warmth felt in the cool CO₂ baths at 27.5° to 33°C. (81.5° to 90.4°F.), and ascribe the increase of respiratory volume to the same skin irritation. There was an increase in the minute volume in the cardiac output

4.8 before the bath, to 5.9 liters per minute in the bath and an average increase of the output per beat of the heart from 98.5 c.c. to 128 c.c.

Too much stress should not be laid on these experiments, as the method employed was one using nitrous oxide as the inert gas for rebreathing, instead of the more accurate acetylene gas. They were performed in 1922 and the opinions expressed could not be influenced by Hediger's¹⁸ work in 1928 on CO₂ absorption. It is most desirable that these experiments should be repeated, using the newer acetylene method.

Bornstein, Budelmann, and Ronnell¹⁹ recently, in estimating the minute volume of the heart under the effect of various baths, found that the warm plain water baths at 38° to 39°C. (100.4° to 102.2°F.) increased the cardiac output per minute between two and three times. The technic used was Grollman's,¹⁰ but using nitrous oxide instead of acetylene. Winterstein and Fraenkel-Tessmann²⁰ repeated these experiments also at Bad Oeynhausen on the effects of these baths of 36 to 38°C. (96.8 to 100.4°F.) and employed the same technic, but used the acetylene gas. The results obtained showed that the influence of these warm baths on healthy persons, as tested by Grollman's acetylene method, produced either no change or a diminution of the cardiac minute volume.

Bornstein et al.,¹⁹ tried the effect of small amounts of CO₂ in inspired air, 0.25 per cent to 0.7 per cent on the minute volume of the heart. They report in some instances a slight effect but otherwise no effect. They, unfortunately, used the nitrous oxide gas in these experiments and express surprise on how little is the effect on cardiac output of small amounts of CO₂ in this inspired air. These results indicate that smaller amounts of carbonic acid, than can be demonstrated as changes in pH by most methods employed may well pass through the lungs into the arterial blood and stimulate reflexly the respiratory center through the carotid glomerulus since Heyman et al.,⁵ as already mentioned, have brought forward the evidence of such a possibility. But there does not seem to be evidence yet produced which has convincingly shown that there is an increase of CO₂ in the arterial blood, after the increased peripheral CO₂ absorbed in the bath has passed through the lungs.

DISTANT HUMORAL ACTION OF NERVOUS STIMULATION

There is, however, a possible explanation which may solve this puzzle. The vasodilator nerves in the fore and hind limbs of animals have their ganglion cells in the posterior spinal ganglia and they are distributed with the sensory nerves. Bayliss²⁸ from his experiments believed these were not efferent nerves but were identical with sensory nerves, and endeavored to explain their vasodilation action through their capacity for antidromic conduction. Kuntz¹³ states that the effects of antidromic conduction have been observed only on blood vessels and always involve vasodilation and expresses doubts of the antidromic theory. Both Kuntz¹³ and Alles¹⁴ quote Kuré and his co-workers as having brought forward histological evidence that every spinal segment has fine medullated fibers in dorsal roots which should be classified with the parasympathetic innervation of the craniosacral segments.

Alles¹⁴ in reviewing the physiological action of the choline derivatives also draws attention to the fact that

in antidromic vasodilation Lewis and Marvin had already definitely proven the presence of a humoral agent by showing that the amount of vasodilation resulting from local stimulation of an organ is dependent upon the amount of blood flowing through it and becomes marked when the flow is stopped. They ascribed this action to a histamine like substance. Dale considered this substance to be acetylcholin or a corresponding substance and Kibjakow has observed that the limb blood of the cat after stimulation of the related spinal root fibers produces a vasodilation of an isolated rabbit ear preparation which effect is related to acetylcholin and opposed to that of histamine.

Dale and Gaddum²¹ have also produced further evidence that the antidromic stimulation of the parasympathetic vasodilating nerves in the periphery produces acetylcholin in these areas. More recently Feldberg, Minz and Tsudzimura²² have carried still further the demonstration of the humoral action of the autonomic system by showing that impulses traveling down the splanchnic nerve fibers to the suprarenal medulla are chemically transmitted to the effector cells by the liberation of something indistinguishable from acetylcholin. This seems to be the first evidence that the preganglionic impulses transmitted by a sympathetic nerve, which the splanchnics

undoubtedly are, liberates acetylcholin. It hitherto has been considered as a transmitter only of parasympathetic effects. These workers also show that by protecting with eserine the acetylcholin liberated in the suprarenal medulla, the effects of the acetylcholin are shown on the arterial blood pressure and the secretion from the salivary glands of the same animal.

Minz²³ quotes Fuhner as having shown that the effect of eserine is specific in its inhibition of the action of the tissue esterase on the acetylcholin. Fuhner²³ also has shown that the acetylcholin is protected from the esterase by an increased hydrogen concentration, an increased CO₂ tension. Whether the acetylcholin-like substance secreted by the sympathetic splanchnics is similar to that secreted by the parasympathetic or only analogous, as in the case of the two sympathins, remains to be proven. In testing the acetylcholin and other cholin esters in these tissue solutions, the tests are made largely by the comparative action of these substances on the muscle of the leech (*Hirudo Medicinalis*), or on the abdominal rectus muscle of the frog and not, as a rule, differentiated chemically.

Kraitmair,²⁴ studying various cholin esters, has found one, carbaminoylecholin, an ammonium ester of cholin, which acts biologically in all respects similar to acetylcholin and is stable in solution easily soluble, and of extraordinary toxicity and active in doses which compare to those of hormones and vitamins. It does not require the protection of eserine, as it is stable in the tissue solutions and only slowly destroyed. Acetylcholin, however, is the only cholin ester yet recognized to be connected with the effects of nervous stimulation, but that does not indicate others may not be found.

It is but the logical development of the findings of Loewi¹⁷ and Cannon³ to conceive of the acetylcholin already demonstrated to exist in the periphery due to the action of the parasympathetic vasodilator nerves, being protected by the increased hydrogen concentration from the inflowing CO₂ as being carried in the return venous blood to the heart, even though the venous blood still is alkaline, stimulating thus an increased vagal action in the heart. This also helps to explain the increased action of the proprioceptive reflexes of the heart, i.e., those originating in the organ with

their actions confined to it, as the Bainbridge reflex,²⁹ increasing the blood flow through its chambers, and Anrep and Segall's¹¹ reflex increasing the blood flow through the coronary vessels. Both these reflexes are of vagal origin and would thus act without outside parasympathetic or sympathetic stimulus.

As Tschermak's test shows, degenerated hearts are more than normally sensitive to the influences of the autonomic nervous system and in degenerated hearts suffering the syndrome of angina, they are dominated by the influence of a disturbed equilibrium through increased action of the sympathetic system, which produces pathologic reactions, since normally the nervous balance in the heart is under the dominance of the vagal function more than that of the sympathetic. Using the CO₂ to protect the chemical conveyance to the heart of the products of the parasympathetic nerve stimulation of the periphery to bring about more normal equilibrium seems today to be the most logical solution of the problem.

ACTION ON THE CORONARY CIRCULATION OF THE CO₂ BATHS

Recent investigations have brought forward much interesting evidence showing the increase of cardiac output through the influence of the various baths. The special influence of the CO₂ baths at 32.5° to 34°C. (90.5° to 93.2°F.) is best understood by comparison with the effects of other baths. In plain water baths, slightly warm, 36° to 38°C. (94.8° to 100.4°F.) just above the indifferent temperature of 34° and 36° C., Winterstein and Fraenkel-Tessmann,²⁰ as already quoted, found that there was either no change or else a diminution of minute output. Budelmann²⁵ on the contrary, reports a moderate increase of the minute output in normal hearts in plain water baths of 37°C. to 38.5°C. (98.6°F. to 101.3°F.).

Voigt²⁷ shows that the results of a single arm bath or of two, three, or all four limbs, is the same as in the whole body bath. The increase of circulation, the rise of the minute volume, the pulse frequency, and rise of arterial pressure, are dependent on the extent of skin area used in the bath. In the single arm bath, the increase per beat was slight, but distinct, the pulse rate also increased slightly and the minute volume increase was also distinct, but in the other baths, using two or more limbs,

the increase per beat rarely occurred and the minute volume was obtained through the increased cardiac acceleration. The work of the left ventricle, however, was uniformly increased.

This is an interesting difference from the heart's mechanism in the CO₂ bath since the coronary flow is not augmented by increased cardiac rate.²⁰ It is increased by the rise of arterial blood pressure and by increased output per beat. In the hot plain water bath the increase of the cardiac output is through the stimulation of the sympathetic system, through the accelerators, by increasing the rate per minute while in the CO₂ bath with its diminished pulse frequency, the increased output is through the increase per beat, the ventricular output being stimulated through the normal vagal reflexes.

Voigt²⁷ emphasizes that with the gradual increase of the heat in these hot plain water baths, it is usually safe to use them in cardiac conditions, but they must be outlawed in angina pectoris. This is clinical testimony of the difference between the effect of the stimulation from these and the CO₂ baths. It is also claimed that the cutaneous stimulation of the heat in these baths is equivalent in its effects to the skin and tissue reaction from the CO₂. The evident sympathetic reaction on the cardiac rate mechanism from the heat reaction in the skin rules out this viewpoint as the vasodilator reaction at the periphery from the CO₂ is a parasympathetic reaction and is followed by an increased vagal reaction in the heart and not a sympathetic one.

Grollman¹⁰ shows, as the increased venous return blood from the periphery begins to pour into the heart, that it is an essential, but not the only factor in the increased cardiac output. The peripheral vascular dilation in the skin in the CO₂ baths requires increased distribution of blood from somewhere, probably the splanchnic area. It may be from the liver as there is a sluice-way mechanism in the liver, as shown by Bauer, Dale, et al.,²⁶ allowing a discharge of accumulated blood in its bodily redistribution. This is under sympathetic control and produced by the action of adrenalin. The stimulation of the sympathetic peripheral constricting vascular mechanism may well produce the reflex for a redistribution of blood.

Budelmann²⁵ brings forward some interesting results of his measurements of the

cardiac minute output in the slightly warm plain-water and CO_2 baths and shows that in the bath there is an immediate venous back flow to the right heart, in both normal and damaged hearts, producing a fall in vital capacity in the lungs and a general rise of venous pressure. This leads to an increase of blood in the right heart. If the compensating power of the left ventricle is functionally capable of accepting this sudden increase of load, it will with increased output per beat and minute volume soon accommodate itself to its increased output. In a normal heart, in about seven minutes, the vital capacity returns to its original level, but the venous pressure retains through the bath an increase of 2 to 3 cm. above its starting point. If the left ventricle fails to compensate, there is a continued fall of vital capacity and an increase of venous pressure and the failing left ventricle cannot increase its output and there is a sudden collapse of blood pressure and accelerated pulse.

In the plain warm baths and sometimes in the CO_2 baths, there is at first a slight increase of pulse rate indicating that the pressure of blood in the right auricle is causing the Bainbridge reflex²⁹ to act; i.e., the pressure causes a relaxation of vagal control, allowing the sympathetic accelerators to increase the rate that the blood may be hurried on through the chambers of the heart and thus assist the left ventricle to empty itself by an increased output per minute before it may be able to increase its output per beat. As soon as there is an increase in arterial blood pressure, there is an increase in coronary flow; this occurs in ratio to the mean blood pressure, i.e., half the sum of the systolic and diastolic pressures.³⁰ As soon as there is an increase per beat of the cardiac output, there comes into play the Anrep and Segall¹⁴ reflex from a relaxation of the vagal constrictors of the arterioles, and capillary vessels, increasing greatly the coronary circulation in the whole myocardium. Both the Bainbridge and the Anrep and Segall reflexes are vagal reflexes as they do not occur experimentally if the vagi are cut.¹¹

The CO_2 baths show earlier and characteristically a less frequent pulse rate than the plain water warm bath, due to the increased parasympathetic action on the mechanism of the heart produced, if our theory is correct, by the humoral action of

the autonomic system through the transference of the acetylcholin from the periphery. The action of the CO_2 bath on the heart is analogous therefore to physical exertion retaining the advantages of the increased cardiac output per beat and increased nourishment through vigorous improvement in its coronary circulation, but with no bodily muscular exertion, no excessive drive of circulation, through stimulation of the sympathetic system. The arterial blood leaves the heart for the periphery and goes to its peripheral capillaries without the accumulation of a mass of lactic acid from the muscles to be oxydized and the blood also returns to the lungs better oxygenated than after exertion and there is less need for increased pulmonary ventilation. The heart therefore is improved by the CO_2 bath at a minimum outlay to itself and with a maximum gain to its myocardial condition.

CONCLUSIONS

1. In the CO_2 baths the CO_2 is absorbed by the skin and discharged by the lungs, there being no satisfactory evidence to show that the CO_2 is carried by the arterial blood from the lungs.

2. The autonomic nervous system acts by a humoral distribution of chemical substances to produce its nervous stimulation.

3. These chemical substances can be secreted in one area of the body and be carried by the bloodstream and produce their action in a more or less remote area.

4. There seems to be a probable, though as yet unproven occurrence of this remote humoral action in the CO_2 baths. The acetylcholin secreted by the parasympathetic peripheral dilator nerves, protected from destruction by the greatly increased CO_2 tension, being transported from the periphery by the venous blood, to act on the vagal mechanism of the heart.

5. Plain water warm and hot baths and CO_2 baths increase the cardiac output. The plain water baths act chiefly through stimulation of the sympathetic system by increasing the output per minute, more than the output per beat. The CO_2 bath increases the output per beat through the parasympathetic mechanism of the heart.

Another difference between the plain water and CO_2 baths is that the plain water baths affect the coronary circulation

comparatively little, while the CO₂ baths benefit the heart by increased coronary circulation through increased stroke volume

and with little demand on the circulation from increased bodily metabolism.

SOVIET PLANS MEDICAL ZOO

A mammoth zoological garden whose inhabitants will annually be sacrificed to the cause of science at the rate of 9,000 dogs, 7,000 cats, 21,000 rabbits, and 16,000 porpoises will be only one feature of the new medical center which the Soviet plans to start building on the outskirts of Moscow this coming spring, according to a dispatch from Moscow to the *New York Sun*.

According to plans this will be the medical center of medical centers, and will automatically bring the Soviet Union to the front in the field of experimental medicine. The entire layout will cover about 1,000 acres, comprising separate but co-ordinated institutes devoted to research in morphology, physiology, psychology, biophysics, biochemistry, and pathology.

The headquarters building will contain a library of 600,000 volumes and an auditorium seating 1,500 people. A clinic will contain 600 beds and there will be almost one laboratory for every patient, allowing the maximum amount of attention to each case. Apart from the laboratories and clinic will be a section of apartment buildings to accommodate 12,000 people, including 5,500 doctors, research workers, and nurses.

One of the ultra-modern features of the center will be a laboratory in which healthy patients may be subjected to the atmospheric conditions of various climates, ranging from

the arctic to the subtropics, while doctors study their reactions. Thus it will be possible to determine, theoretically at least, what diets are best in various climates for people engaged in various activities.

In "the clinic of healthy and sick man" scientists will determine the effect upon people in various states of health of working, eating, and sleeping.

Before drawing up plans for this ambitious center the All Union Institute of Experimental Medicine sent a commission to the United States to study the work of the medical centers at Cornell and Columbia and the Rockefeller Institute, and it is probable that a representative of the New York city health commission will visit Moscow next spring to give consultation.

While the Soviet Union is still greatly handicapped in the field of practical medicine by lack of capable physicians and of medical supplies this condition has not been allowed to retard progress in the province of experimental medicine.

The plans of the Soviet for the development of the system of "state medicine" are almost limitless and the new medical center will form an indispensable part of the system.

The buildings and the equipment, much of which may be bought in the United States, will cost about 150,000,000 rubles. The center should be in full operation by 1939.

TREATMENT OF DIABETIC COMA

HERMAN O. MOSENTHAL, M.D.

New York City

The principles guiding therapy in diabetic coma have changed completely during the last decade. Ten years ago, acidosis was the synonym for diabetic coma accepted by the clinician. At that time, the main effort at controlling this disturbance, which was usually fatal, was the administration of bicarbonate of soda in large amounts by mouth, vein, rectum, and hypodermoclysis. This was done for the purpose of forcing the elimination of accumulated acid by way of the kidneys and providing an adequate amount of base for internal respiration. Bicarbonate of soda is just as useful today in this regard as it was ten years ago, but it has become unnecessary since diabetic coma is no longer treated as an acidosis but as a diminished power of the body to assimilate glucose.

Insulin, perfected by Banting, Best, and the Toronto group of scientists, has enabled physicians to manage diabetic coma, not as a poisoning by acid, but as an intoxication due to the marked impairment of the ability of the tissues to utilize glucose. This principle was appreciated long ago but it could not be applied because, without insulin, clinicians could not light the fire of the carbohydrates in which the fats must be consumed. This can be accomplished now, so successfully that most cases can be revived within a few hours.

The most important point in the successful treatment of diabetic coma is the proper use of insulin; this matter will be taken up first and the remaining parts of the treatment subsequently.

The early treatment of this condition is very essential. Diabetic patients should be instructed that if they have an infection if they become subject to nausea or vomiting, if their respiration becomes deeper than usual, or if they feel out of sorts in any way, they should inform their physician immediately.

Insulin should be administered in comparatively small doses and at frequent intervals. In this way, more carbohydrates are digested per unit of insulin than with a single large dose, a huge amount of insulin

at one time—100 to 400 units as have been given—may result in hypoglycemic reactions for many hours subsequently, this is a real danger which has to be guarded against, it is worth remembering that more insulin can be given with an almost instantaneous effect on the carbohydrate metabolism, but insulin cannot be removed from the body, nor can extremely large doses be readily compensated for by the ingestion and intravenous injection of glucose. The first dose of insulin should be given partly by vein to insure immediate results, and partly subcutaneously so as to prolong its action, 20 units by vein and 20 units subcutaneously is usually sufficient.

After this initial treatment insulin in doses of 10 to 20 units should be given subcutaneously every hour or two hours. The amount and the frequency of the doses are regulated in the first place according to two signs: the depth of the respiration is a good measure of the persistence and intensity of the acidosis, another criterion of the effect of insulin upon the coma, naturally, is the degree of recovery from the unconscious state.

In the second place, the result produced by the insulin should be judged by an hourly or two hourly careful examination of the urine. This should be obtained by catheter if necessary. The urine is examined for sugar and for diacetic acid. If glucose persists in the urine in appreciable quantities, the hourly or two hourly subcutaneous injection of insulin is continued. When sugar is present in the urine in only small amounts and there is need for further insulin effect, then glucose must be given by mouth, vein, or subcutaneously in order to furnish the injected insulin sugar upon which it can act. The subject of the administration of glucose in diabetic coma will be taken up in greater detail later on.

The presence of diacetic acid in any specimen of urine as shown by the ferric chloride test calls for the utilization of more glucose and consequently the continued use of insulin. The same is true of the persistence of the physical signs of

coma; viz.: unconsciousness and the deep breathing.

The careful and painstaking procedure according to this outline usually results in the recovery of consciousness within a few hours.

The equipment necessary for this treatment should be kept in readiness by every physician. It consists of two four-ounce bottles—one of Benedict's solution and one of ferric chloride solution of 10 per cent or stronger—four test tubes preferably of pyrex glass so that they will not break on heating, one alcohol lamp, 400 units of insulin, and a hypodermic syringe. This is all that is essential for emergency use.

The determination of blood sugar and the CO_2 combining power of the blood, are exceedingly valuable and comforting determinations for the guidance of treatment. However, they are not absolutely necessary. Furthermore, unless the patient is in a hospital with adjacent and functioning laboratories, the reports would come in too slowly to be of much help. Decisions must be made regarding the regulation of insulin and glucose every hour or two, and the results of laboratory tests that are reported late during these intervals, are past history and not of great value for the control of the immediate handling of the situation.

Although it interrupts the flow of thought, I should like to call attention here to a matter which Dr. Bolduan of the Department of Health in New York City called to my attention. Dr. Bolduan sent out questionnaires regarding the diagnosis and treatment of cases of diabetic coma which terminated fatally. Many of the answers indicated that the patients had succumbed to diabetic coma without receiving insulin.

According to the answers given, this astounding fact apparently is not the error of the physicians, but is due to the unwillingness of patients or their families to submit to insulin therapy. Why there should be this deep-seated objection to the life-saving benefits of insulin, it is difficult to understand. However, from these questionnaires it becomes perfectly evident that the education of diabetic patients and their families must be carried out more effectively. The same antagonism to the use of insulin is being encountered as there has been to other life-saving measures such as vaccination and diphtheria antitoxin.

When the urine becomes free of diacetic acid, the patient returns to consciousness and the breathing is no longer deeper than normal, then insulin may be given three or four times a day and an appropriate diabetic diet resumed.

While the insulin brings about the adequate utilization of glucose, and through this, the complete oxidation of fatty acids and does away with the acidosis and coma, there are certain urgent effects of the inability to assimilate glucose in the comatose patient that must be taken care of. Some patients never recover consciousness although they are relieved of the acidosis, and others succumb after the coma is set aside, to the ravages which the diabetes and acidosis have imposed upon them. Such complications are attributed principally to dehydration. The dehydration comes about in diabetes largely through the polyuria incident to the elimination of glucose, and to the loss of basic material accompanying the excretion of excessive quantity of acids in the urine. Marked dehydration results in a rapid pulse rate, low blood pressure, impaired cardiac power, diminished surface temperature, oliguria, and constipation.

Great care must be taken to meet these complications so as to prevent a fatal issue which may occur even though the coma itself has been overcome.

Every patient should be kept as warm as possible by the usual methods. Fluids should be administered in good quantities by mouth, subcutaneously, or intravenously; possibly all three methods may be employed. At times there is vomiting or gastric distention. In this event the stomach may have to be washed out and only the intravenous and subcutaneous routes used for the administration of fluid. The fluid should consist of saline solution, according to the precepts given by Peters and his co-workers, to aid in the restoration of the proper acid-base equilibrium of the body and also to favor the retention of fluid.

There is some controversy as to whether glucose should be routinely administered, or not. It has been the author's belief that glycosuria favors polyuria and therefore there is a loss of fluid to the body when sugar is present in the urine. Furthermore, it would seem entirely superfluous to add glucose when the quantity of insulin administered to the patient has not

succeeded in utilizing the excess of sugar which already exists within the body. Consequently, glucose has been given only when the urine showed a low concentration of sugar, approximately less than 0.5 per cent, and when further immediate administration of insulin was indicated. This method of balancing insulin and glucose has proved to be satisfactory.

For the cardiovascular involvement, we have resorted to digitalis with the idea of digitalizing the patient within 24 to 48 hours. When insulin was first employed in the treatment of diabetic coma, it was our experience that some of the cases succumbed to pneumonia after the coma had been set aside. The impression was gained that this was the result of pulmonary congestion existing during the period of unconsciousness. Since digitalis has been resorted to, the pneumonic com-

plication has been absent. The rapid pulse rate, the low blood pressure are nearly always present in diabetic coma and are ample evidence of the need for cardiovascular stimulation.

If rapid response is not obtained after the first rush of activity in caring for these patients is over, it is necessary to think of possible complications, as the presence of infection, an over-active thyroid, apoplexy. Such co-existing diseases have to be met on their own grounds and given due attention.

The treatment of diabetic coma has, through the availability of insulin, become one of the most simple and direct therapeutic problems in medicine. It is exacting in its demands upon the physician, the nurse, and the patient, but the splendid results amply reward the effort.

889 LEXINGTON AVENUE

DIABETIC REGIME IN SURGICAL CASES

ARTHUR H. TERRY, M.D.

New York City

The following rules, prepared for the control of diabetes in surgical cases before and after operation on diabetics at the Beekman Street Hospital, are given with acknowledgment of helpful suggestions from Dr. Leland McKittrick of Boston and Dr. Julian M. Freston of New York.

A. CHRONIC CASES

The day before operation: Regular diabetic diet covered by insulin so as to make sugar-free or nearly so. Do not lower blood sugar quickly, especially in old arteriosclerotics, and do not aim for too low blood sugar before operating. Diabetics stand surgery better with a fair amount of blood sugar—150 to 200 mgms. is probably ideal. This is frequently associated with faint traces of sugar in the urine—cloudy green reductions, or even a little orange color.

The day of operation: Fluids—broth, tea, coffee, and water—are forced until two or three hours before operation. Usually no insulin before operation if sugar and acidosis are controlled. If not controlled, treat every hour or every two hours by orange juice or ginger ale (6 ounces) and insulin according to color

formula in urine—15 units if red reduction, 10 units if yellow reduction, 5 units if green reduction, until controlled. If this method does not control acidosis, then treat as in acute cases, as gastric absorption may be delayed due to nervousness. Orange juice taken two or three hours before operation may be vomited unchanged during operation.

Postoperative: 50 grams of glucose in 1000 c.c. saline in operating room, or as soon as patient has reached his own room, together with insulin—20 units subcutaneously. *One hour later*, 5 or 10 units of insulin according to the severity of the case. Patient should be catheterized and specimen discarded as quantity of sugar due to usual spilling immediately following infusion may be poor index to insulin dosage, permitting too much insulin and consequent hypoglycemia. *Two hours later*, insulin 15, 10, or 5 units according to color formula in urine probably catheterized. *Four hours later*, repeat urine and insulin according to color formula. *Six hours later*, carbohydrate is begun by mouth with insulin p.c. according to amount taken and color formula in urine.

AN EXAMPLE: Gruel—4 ounces (carbo-

hydrate 12) or gingerale—6 ounces (carbohydrate 10)—insulin 5, 10, or 15. Repeat every 2 hours until regular or soft diet with insulin to cover. If not taking fluid by mouth six hours postoperative, repeat glucose by vein with insulin. 100 grams of carbohydrate by mouth or vein each twenty-four hours postoperative. May continue 50 grams of glucose in saline by vein with insulin regime B.D. ad lib if necessary because of vomiting or acidosis. Watch and wash the stomach.

B. ACUTE CASES—DEHYDRATION, VOMITING, AND ACUTE INFECTIONS

Surgical success depends on early operation. Don't wait for ideal conditions. Best treatment for acidosis is removal of infection. Usually cannot get sugar-free or low blood sugar.

Surgical Diabetic Régime—Preoperative: Wash out the stomach in acute abdominal cases or any severe acidosis. Give 20 units of insulin subcutaneously and 50 grams of glucose in 1,000 c.c. saline and go ahead.

Postoperative: Treatment same as that given for chronic cases except that more fluid may be given by vein or additional saline subcutaneously. Rectal absorption doubtful.

Twenty-four hours postoperative: Liquid diet ad lib with insulin and food according to color formula—gingerale, tea with or without sugar, broth or gruel preferable to orange juice.

C. ALL CASES

All cases are treated according to severity, mild cases and minor surgery requiring only small amounts of insulin with glucose by mouth before and after operation.

Blood Sugar: Preoperative ideal: 150 to 200. Postoperative ideal: 110 to 160 because infections heal better with a low blood sugar.

Urine: Preoperative ideal: few tenths of glucose. Postoperative ideal: sugar-free.

Anesthesia: Coma in surgery may be caused by chloroform, too much ether, restriction of carbohydrates and water. Spinal anesthesia, gas and oxygen, or ethylene gas are probably best.

Exercise: In bed as soon as possible, out of bed as soon as permissible.

Sedatives: A restless patient probably needs fluids or glucose. Better restless upstairs than at rest downstairs.

161 EAST 64TH STREET

PROTESTS PAY

There is a lesson for physicians attending C.W.A. employees in the experience reported by the *Westchester Medical Bulletin*. It seems that early in the summer physicians who had been certified by the County Society to render compensation services for employees of the Civil Works Administration began to receive payments on the bills they had submitted to the C.W.A. All of these bills had been arbitrarily cut by the U. S. Employees Compensation Commission, some of them as much as 50 per cent and a remittance sent to the doctor with a curt note to the effect that he could take this payment in full settlement of his claim and like it.

On July 25, the committee, with the knowledge of the local C.W.A. administrator, issued a statement of protest to the Compensation Commission in Washington, asserting that this was an outrageously high-handed policy. The Commission responded on July 31 requesting the names of a number of cases illustrating the protest. On August 8 the committee submitted about twenty cases and requested a report on them. To date they

have heard nothing further from the Commission, but have learned with considerable satisfaction that some of the local physicians have received supplementary checks on accounts which they had been told were "settled" by the first payment.

Nothing indicates that these supplementary payments are a national policy of the Commission and this shows very concretely the value of the Society's making strong protest whenever its members are imposed upon.

The astonishing fact that "the sewage from population centers having 8,393,000 people is discharged untreated into the waters of the State," is revealed in a report of the State Planning Board sent to the Legislature by the Governor. And "in addition, there is much preventable pollution from industrial wastes. Legislation for the control of pollution should be strengthened."

The planning board, headed by Dr. A. R. Mann, provost of Cornell University, was created last March at the instance of the National Resources Board, and will submit its final report to the Legislature April 1.

GASTROJEJUNAL OR MARGINAL ULCER

D. PHILIP MacGUIRE, A B, M D, F A C S.

*Assistant Clinical Professor of Surgery of the New York Post Graduate Medical School and Hospital,
Columbia University*

*From the Department of Surgery, New York Post Graduate Medical School and Hospital,
Dr. Charles Gordon Heyd, Director*

Gastrojejunal or marginal ulcer presents a condition which is admittedly difficult but is of real interest to the surgeon. The operation of gastrojejunostomy, at one time regarded as one of the most beneficial of surgical procedures, is now considered by many surgeons as an unjustifiable measure in the treatment of peptic ulcer especially when confronted with hyperacidity, patent pylorus, and negative six hour barium meal retention as found on x-ray examination. On the continent of Europe gastric resection has largely replaced the short-circuiting operation, but in Great Britain and in America, the surgeons have not swung over to the more radical practice, at least in the treatment of duodenal ulcer.

Apart from the persistent dyspepsia which is the common lot of sufferers from gastrojejunal or marginal ulcer, certain alarming and disabling complications are frequently encountered. The more important of these will be mentioned.

Recurring hemorrhage is the most frequent and the most difficult phase to treat. It calls for surgical treatment preceded by blood transfusion.

Perforation into the free peritoneal cavity in gastrojejunal or marginal ulcer, while uncommon, is always serious owing to difficulties of satisfactory closure without compromising the gastrojejunal outlet. A second operation, which presents a formidable technical problem, is usually required to treat the ulcer if the more immediate dangers are survived.

Subacute perforation with the formation of an inflammatory mass, situated to the left of the umbilicus, calls for conservative treatment until such time as the inflammatory reaction has subsided. Thereafter, surgical interference must be undertaken. If the local conditions permit, the region of the anastomosis must be freed and a partial gastrectomy performed. When the patient's general condition is poor, and inflammatory infiltration of the mesocolon and root of the mesentery is

such as to present formidable obstacles to a safe resection, the author has found that reasonably good results follow a double short-circuiting operation, viz., a gastroduodenostomy to exclude the old ulcer, and a duodenojejunostomy to exclude the region of the gastrojejunal or marginal ulcer.

PENETRATING GASTROJEJUNAL OR MARGINAL ULCER

The usual location of the ulcer is just at the stoma, alongside of it or just beyond. Occasionally, however, the ulcer may be found in the jejunum proximal to the stoma. In such cases, it may penetrate into the mesocolon and the posterior abdominal wall, just as a posterior gastric ulcer penetrates into the pancreas. Excision of such a penetrating ulcer may lead to a wound of the superior mesenteric vein and it should not be attempted. In a very pronounced example of such an ulcer in the proximal loop, a completely satisfactory result followed the removal of the gastroenterostomy stoma, closure of the stomach and the jejunum, the establishment of a gastroduodenostomy opening to exclude a stenosing duodenal ulcer, and a duodenojejunostomy to short-circuit the gastrojejunal ulcer.

One of the most important complications in our series of cases is the occurrence of secondary duodenal stasis which is verified by x-ray examination in both the pathological and clinical pictures of many cases of gastrojejunal ulcer and especially cases of long standing. The tendency to thickening and fibrosis in the region of the stoma leads, on the one hand, to a gradual narrowing, and in some cases a potential, if not actual, occlusion of the gastroenterostomy opening, and, on the other hand, to an inflammatory induration of the root of the mesentery which interferes with the efflux from the duodenum. In the treatment of such old-standing cases special measures must be taken to drain the partially obstructed duodenum if complete

relief is to be gained. In some cases, drainage of the duodenum by the establishment of a duodenojejunostomy stoma may be all that is necessary; in others, this operation must be associated with a direct attack on the gastrojejunal ulcer and the original stoma.

PATHOLOGY

The pathological characters of these ulcers are identical with peptic ulcers seen in the stomach or duodenum. A few cases of acute ulceration are seen; these are either operated upon for severe hematemesis or are discovered postmortem after a perforation or death from some other cause; they are, therefore, usually found shortly after operation. In a series of cases given by Walton,¹ he found, that in 3 of the 79 examples, there were intervals of one month, one month, and five months, respectively, after the first operation. In such cases there are one or more areas of sharply cut but irregular ulceration involving only the mucosa but tending to encircle the anastomotic area. The edge of the mucosa may be free or only lightly attached to the underlying tissue and there is little or no induration around. The surface may be covered with a sloughing material, and small areas of hemorrhage or a small eroded vessel may be visible. Rarely in these early stages, an acute ulceration may progress to perforation, in which case, a relatively acute necrosis with but slight reactionary induration is seen.

Long-standing ulcers have all the characteristics of the chronic peptic ulcer, being deeply cut and penetrating. They tend to be circular, the mucosa is turned in and attached to the edge of the destroyed muscle, the floor is formed either of thickened peritoneum or some adherent neighboring structure, and if sections of it are cut there is a complete absence of muscle fibre. There is much infiltration and fibrosis, at first, of the surrounding wall of the stomach and jejunum, and later of adherent tissues such as the mesocolon, or anterior abdominal wall. They are usually single and may be localized or extend nearly around the anastomosis. If single they are most commonly at the extremities where the afferent or efferent loop is united to the stomach, but in some of the cases where the primary operation was performed, they were situated at the middle

of the anastomosis. In some cases they are multiple, as many as three or four having been reported.

ETIOLOGY

It has long been recognized that these ulcers are much more common in males, and this sex distribution seems to be more evident in the more recent series. In Paterson's series² the sex was mentioned in 50 cases, 39 being men and 11 women. Hurst and Stewart³ state that there are about 6 males to 1 female. Walton¹ reports that in his 79 cases, there were only 7 females, and in 30 in whom he had performed the first operation only 1 female. Huddy⁴ found that in 129 cases of duodenal ulcer that 56 (42 per cent) showed a family history. Hurst and Stewart³ have shown that this inherited tendency goes deeper than the actual ulceration and that it is the variety of gastric function which runs in the family, a view which is supported by Apperly and Norris⁵, who investigated carefully a series of families comprising 86 individuals.

Most of these cases consisted of men of middle age. No definite reason can be given just why this condition occurs more frequently in men than in women. The important factor as to the cause of this condition has not been definitely proven by clinical experiment but seems to favor the presence of hyperchlorhydria. The following men greatly contributed facts through their experiments on animals to attempt to prove this to be true, Montgomery,⁶ Mann and Williamson,^{7,8} Matthews and Dragstedt.⁹

SYMPTOMS

Frequently this condition is not diagnosed until perforation or penetration has occurred. In the most recent series these complications are much rarer, for the symptoms of non-penetrating ulcers are now well recognized and the condition treated.

Clinically, there are two groups. In the first, the dominant symptom is hemorrhage. This may occur as a mild hematemesis or melena shortly after operation, or the patient may continue in a fair state of health for a year or more and then have a sudden severe loss of blood, generally in the form of melena. Walton¹ believes that all such cases have marginal ulceration, but at this stage, it may be only

acute, it may be readily overlooked at operation or even, indeed, at a postmortem examination

In the more common variety, there is in the earlier stages only a minor degree of discomfort, fullness, or flatulence, which is later replaced by a definite pain, at first thought to be that of the old duodenal ulcer. It simulates the original lesion in that it becomes periodic. It is severe, occurs late after food, is relieved by food, and often wakes the patient at night. A careful investigation will show, however, that the pain differs from that of a duodenal ulcer in that it is often referred to the lower abdomen, and especially to the left iliac fossa, and that vomiting, which is so rare a symptom with uncomplicated duodenal ulcer, is often present and generally gives transitory relief to the pain. In the later stages, as the ulcer penetrates, the pain becomes more and more severe and much more constant. It may, indeed, become agonizing and the patient may pass into a stage of deplorable misery. In the cases reported by Walton,¹ 73 of the 79 experienced pain. It must, therefore, be regarded as the most frequent and characteristic symptom. Vomiting, generally giving temporary relief, was present in 46 cases. In the earlier stages, the patient retains his appetite and the test-meal shows a high acidity. Later, when the pain becomes more severe, his appetite may begin to fail.

SUMMARY

(1) It has been frequently stated by writers and speakers that a diagnosis of gastrojejunal or marginal ulcer is a very difficult one to make by x-ray examination. The author believes that the difficulty arises from the lack of close co-operation between the internist, surgeon, and roentgenologist. It is his opinion that the elimination of this condition requires the greatest amount of united study and consultation by these experts to make a correct diagnostic conclusion. In our personal experience, although the direct evidence of gastrojejunal or marginal ulcer is lacking from the x-ray standpoint, nevertheless, the indirect evidence must be fully appreciated since we are all aware that the roentgenologists often overlook the diagnosis of ulcers, especially duodenal ulcers, which would seem fairly large on visual examination after opening the abdomen.

(2) It is the author's belief that it is quite generally conceded that the main factor in producing gastrojejunal or marginal ulcer after a gastroenterostomy is the same as that which produced the original ulcer. Since the characteristic local lesion may be the only discernible evidence of the disease after death, it has consequently been ascribed to purely local causes, viz., vascular, traumatic, bacteriological, and biochemical in addition to the higher acidity which has already been mentioned.

(3) A very high gastric acidity should be regarded as a contraindication to gastroenterostomy—a gastroduodenostomy by a plastic operation if the ulcer is small.

(4) For many years, we have all been aware that septic foci should be cleared up absolutely in all cases.

(5) Partial gastrectomy with removal of the stoma is undoubtedly the method of choice in gastrojejunal or marginal ulcer but gastric sequestration has to be performed when dense adhesions over the distal half of the gastric and first portion of the duodenum make it impossible to perform partial gastrectomy.

(6) The frequent occurrence of secondary duodenal stasis and even ileus and the necessity for the relief of these symptoms is emphasized.

CONCLUSIONS

The various ingenious experimental devices which have been used to produce acute peptic ulcers or erosions in the lower animals, in my opinion, have been of no aid, whatsoever in presenting a possible cure for these ulcers appearing in human beings. The emotional or psychic aspect of the ulcer problem has been frequently emphasized in the past. The relation of the parasympathetic discharges and vagotonia to the primitive emotions has been only partially understood within recent years. One of the most interesting and instructive papers on this subject has been written by Dr. Harvey Cushing¹¹ of Boston. He reported having lost 3 patients suffering from acute perforations of the upper alimentary canal soon after what appeared to be successful operations for the removal of intracranial tumors of the cerebellum. Experimental neurogenic ulcerations, especially those of the peripheral nerve of the stomach, and, secondly, the effect of factors such as dietary indiscre-

tions, excessive usage of tobacco in those highly strung persons who are inclined to nervous instability classified as parasympathetic (vagotonic) caused by undue emotion, or repressed emotion, incidental to continued worry associated with anxiety and heavy responsibility, have results wholly comparable, viz., hyperacidity often leading to ulcer.

We are observing more cases of gastrojejunal or marginal ulcer today than we did ten to fifteen years ago. These cases depress me, personally, because they look the picture of despair, suffer untold mental agony as well as very severe gastric pain and distress. Unfortunately, they have often been told by the operating surgeon that their ulcer disease and all its sequelae will be cleared up by operation. There is no operation that is more difficult technically than that for gastrojejunal or marginal ulcer with its definite fibrosis and the whipping around of sheets of peritoneum surrounding the jejunum. Even entering the abdomen is sometimes a difficult feat since, after the incision has been made down to the parietal peritoneum, rake retractors must be used on the muscles and dissection must be made underneath them, and over the parietal peritoneum in order to find a favorable opening in the peritoneal cavity, since the omentum is adherent to a large portion of the abdominal wall. In many of these cases we have been content to disassociate the gastrojejunal anastomosis by closing the apertures with sutures, dividing the

stomach directly across, and sequestering the distal half since it was technically impossible to remove it.

The author is firmly convinced that almost 20 per cent of the operative procedures of gastroenterostomy performed in those cases of persistent high percentage of acid and with little or no retention of the six-hour Barium meal with a patent pylorus, have been followed by a gastrojejunal or marginal ulceration. Probably 25 to 30 per cent of the gastrojejunal anastomotic operations have been entirely cured. In the remaining 50 to 55 per cent of gastrojejunal anastomosis, the patients have had attacks probably due to indiscretions in diet and alcoholic and tobacco excesses. Undoubtedly the operation of gastrojejunostomy for the cure of gastric or duodenal ulcer is a very serious surgical procedure and should be undertaken only as a last resort after a careful consultation of internists and roentgenologists who feel that the patients are not improving under their treatment.

In those hospital services where gastroenterostomy is the cure-all for all the duodenal and gastric ulcers instead of utilizing gastrectomy of the Continental type, the Deaver-Judd pyloric plastic or Finney pyloric plastic technic, one's imagination is not required to be stretched very far to see the many physical wrecks who will emerge from the condition resulting from gastrojejunal or marginal ulcers associated with its complications and its sequelae.

THE PRESIDENT'S HEALTH SECRET

One marvels at the ability of President Roosevelt to continue healthy while under the strain of grave responsibility and exceptional activity. His attending physician explains the reasons. Twice a year he has a physical examination. He promptly reports to his doctor when he is feeling a little below par. He takes frequent holidays which serve to

change his occupation entirely and which get him away from the constant grind and out into the open. All this has had a great deal to do with his excellent physical condition. Finally, he has a hobby—stamp collecting. It looks, says the *Health Digest*, as if the President has a code for health that many of us might adopt with much benefit to ourselves.

ADVANCED CARDIAC INSUFFICIENCY

Results of Intensive Ambulatory Treatment with Diuretic Measures

MEYER FRIEDENSON, M D

*Adjunct Physician, Montefiore Hospital
New York City*

One of the chief problems in the care of the patient with advanced heart failure is probably not the treatment in the hospital. More likely it is the maintenance of the improved state resulting from hospitalization, in order to avoid the necessity for frequent readmissions. The solution would obviously be of tremendous importance, not only to the patient and to his family, but to the institution as well. A very serious difficulty is the general idea that intensive treatment is not possible unless the patient is confined to the hospital where he can be seen daily, and that such measures are dangerous and should be carried out only with extreme reluctance and trepidation.

This is not true. In a previous report¹ the intensive ambulatory treatment of these cases was advocated, and shown to be not only possible, but quite practical. Instead of the customary method of treating these patients intensively only during severe attacks of congestive failure, and of lessening the treatment during periods of improvement, constant care similar to that in the hospital was given. The object was to maintain the patient in at least the same degree of circulatory efficiency with which he went home. More or less continuous treatment was therefore given in our clinic, which is considered an integral part of the hospital service, and not an isolated unit. It was felt that in this way the patient could be kept out of the hospital for much longer periods of time than would have been otherwise possible.

The fact that the symptoms of advanced cardiac disease have a marked tendency to remission is well known. Since new methods of treating congestive failure appear from time to time it is important to bear in mind the results that may be expected from the present procedures in order to have a standard in evaluating any new approach to the problem. As the conservative measures afford considerable hope of comfort to the cardiac invalid, any new method must promise at least as good results, if not better.

The recent work of Blumgart and his associates² on total ablation of the thyroid gland has again focused attention on this subject. In brief, their work is based on the fact that the complete removal of this organ will reduce the metabolic demands of the body to a point where the diminished circulation due to myocardial failure is sufficient for its needs, and compensation is thus restored. They tried out this idea in a number of cases and feel that they have been rewarded by excellent results. They realize, however, that the operative procedure is not a cure, but a palliative measure, and that the patients must be carefully selected. In their cases the course of the disease had been continuously downward, and the patients were incapacitated even during periods of remission. They felt, therefore, that all conservative measures had been exhausted before they decided on operation.

Our experience has taught us to be more optimistic about the results of medical treatment, and we have obtained improvement, at times spectacular, after months and even years of apparently futile treatment. It is extremely difficult, if indeed not impossible, to say when the conservative measures have been exhausted. Failure after the first, or the tenth attempt at diuretic therapy does not always mean that the next time will not produce results.

The object of the present communication is to show that with the lapse of time and with further experience our belief in the efficacy of intensive medical ambulatory treatment has been justified. At the Montefiore Hospital, we have had the opportunity of studying hundreds of cases of advanced cardiac disease of rheumatic, hypertensive or arteriosclerotic etiology, with considerable cardiac enlargement, many with auricular fibrillation and severe congestive failure of long duration. For our present purpose we have selected only those with recurrent congestive failure.

In treating these individuals as ambulatory patients, special emphasis is laid on the fluid and salt intake and on diuretics.

Our experience has shown that in these cases control of water retention is the most important single factor determining their well-being.

Special diet sheets limiting the fluid and salt intake are distributed and explained in detail. At each visit, the patient is questioned as to his adherence to the diet and reminded of its importance. The protein and the total caloric contents are modified according to individual requirements. Salt, and foods rich in sodium chloride, are prohibited. Only three to four cups of actual fluid are allowed in the daily diet, which, including the fluid content of the food, contains about 1,400 c.c. of total water. This is about as little fluid as it is possible to induce patients to take over any period of time. Frequent use is made of the Karrell diet or of a modification.

The importance of the constant intake of one of the "maintenance diuretics" (urea 45 to 70 gm. daily, or ammonium nitrate 6 to 9 gm.) is stressed. One or the other of these is taken continuously, allowing one day a week rest, *even when there is no longer evident edema*, in order to prevent, or at least to retard the tendency to rapid reaccumulation of fluid which these individuals all show. The urea is given in 50 per cent aqueous solution, and the ammonium nitrate in 40 per cent solution or in 0.5 gm. enteric-coated tablets. In spite of the rather unpleasant ammoniacal taste, the patients are usually willing to co-operate and take these drugs for long periods. Although methemoglobinemia and acidosis during the prolonged intake of the ammonium salts have been described,² these complications have not occurred in our cases.

A mercurial diuretic (salyrgan, mercurpurin, or neptal) is given at frequent intervals when indicated, for reaccumulation of fluid, as shown by gain in weight, for congestive symptoms, for attacks of nocturnal dyspnea, and as a diagnostic procedure for latent edema. We have found that there are few contraindications to the use of these drugs, and that with the proper injection technic, their administration, either intravenously or intramuscularly, is not only safe but remarkably effective.

Digitalis and other drugs as the nitrates, xanthine diuretics, sedatives, and the like, are employed when necessary. Although digitalis usually slows the ventricular rate

in auricular fibrillation, and at times in regular sinus rhythm, we have found it to be insufficient in most of our cases to prevent the reaccumulation of fluid and the exacerbation of symptoms. In certain cases phlebotomy or thoracentesis is performed for urgent indications.

We have attempted to instill into our patients the same attitude to their disease that sufferers from diabetes and other metabolic conditions are taught. They are given detailed instructions as to the significance of their symptoms, of fluctuations in weight, and so on, and as to the purpose of dietary and fluid restrictions, and of medications. In this way it has been possible to secure remarkable co-operation from the vast majority of them with ordinary intelligence. Through a special arrangement we are able to treat individual patients in their own homes if they are temporarily unable to attend the clinic. If it is necessary to see them more often than once a week, additional appointments are made at the hospital at our convenience so that treatment may be properly regulated. These additional visits are often of special importance in preventing sudden increase in congestive failure which may require readmission to the hospital.

Under this régime, by continuous observation of the clinical signs and symptoms, but especially the weight and the ventricular rate, these patients can be kept out of the hospital for long periods of time, able to get about, and attend to light duties. Most of them can be kept thus for months and many even for several years before the inevitable breakdown finally occurs. It should be repeated here, too, that these are not early cases, in their first or second attacks of circulatory failure, but that they have had advanced cardiovascular disease for many years, that they have been in more or less congestive failure for long periods, years, and that they have had numerous admissions to various hospitals before coming to us.

We have under our care in the clinic at present, about 150 patients. Of these, 67 have been in severe congestive failure as described above and it is concerning this group that the following remarks will be made. (Most of the others have congestive symptoms, and even edema, but have never been sick enough to be wholly incapacitated. These are not included.)

These 67 cases by no means represent

all we have treated, but only those who are under our care now. It is to be understood that in patients of this type, regardless of treatment, the mortality over a period of a few years is high. We have observed many more individuals during this time, but patients who have died or who have been discharged from our care for other reasons have not been included here.

Twenty-nine were female and 38 male. Thirty-eight were classified as of rheumatic or unknown etiology and 29 in the hypertensive or arteriosclerotic group. The severity of the disease is clearly indicated by the following facts:

TABLE I

Duration of c	1 25 years
Duration of	1 13 years
Period of obs	1 12 years
Number of at	0-5
Months spent	0-57

Many of these patients have had a number of admissions to other hospitals, not shown in these figures.

Table II shows the periods of time these patients have been able to remain out of the hospital since their last discharge, while under the care of our clinic, and receiving the treatment outlined above.

Six patients have never been in the hospital while under our observation, periods of 4 to 8 years.

TABLE II

1 patient has been out of the hospital 9 years
1 patient has been out of the hospital 7 years
1 patient has been out of the hospital 5 years
3 patients have been out of the hospital 4 years
7 patients have been out of the hospital 3 years
11 patients have been out of the hospital 2 years
26 patients have been out of the hospital 5 months to 1 year
2 patients have been out of the hospital 3 months
9 patients are now in the hospital

It can thus be seen that about one third of our patients, who all had at one time or another very severe congestive failure, have been able to remain out of the hospital for two years or more and roughly 85 per cent of the living patients have already been out at least five months in more or less comfort with restricted physical activities.

This is even more striking if we remember that these 67 cases have been selected as the worst of 150 patients with far advanced cardiac disease that all have had congestive failure for long periods of time, and that in all the ultimate prognosis is extremely poor.

The following case was selected as typical of those with which we are dealing,

and illustrating best the treatment principles involved.

I W, man, aged 54. Diagnosis: Arteriosclerosis, hypertension, coronary sclerosis, cardiac enlargement, arteriosclerotic block, auricular fibrillation, congestive failure.

He was first admitted to the Montefiore Hospital on November 18, 1927, complaining of swelling of the legs of four weeks duration. The essential history was of nosebleeds and headaches for two years and dyspnea and palpitation for one year, followed by swelling of the legs and abdomen. He had already had several episodes during which the symptoms showed exacerbations and remissions, always recurring with physical activity. He had already had an abdominal paracentesis at another hospital.

Physical examination revealed the signs of advanced congestive failure with marked dyspnea, cyanosis, venous distention, pulmonary congestion, bilateral hydrothorax a liver 12 cm below the right costal border, ascites and marked edema of the lower extremities. Later auricular fibrillation was noted.

During the next 2½ years before coming under the care of the clinic, his condition was one of almost continuous congestive failure, with short remissions, and prolonged exacerbations. He was admitted to the hospital three times each time improving after treatment, but returning more waterlogged than ever after a short stay at home. At each hospital admission he was kept in bed and given a diet with restricted fluid and salt. He took digitalis continuously. He consumed 70 to 100 gm of urea daily. Attempts to discontinue it were followed by immediate return of symptoms. He received many injections of salyrgan often as frequently as twice a week, usually followed by good diuresis. The right and left chests were tapped at least twelve times. He was finally discharged March 28, 1930, feeling well, weighing 212 lb.

He now came under the care of the clinic, where for the next three months he did poorly. He was seen at intervals of one or two weeks, took urea constantly and received salyrgan at almost every visit. In spite of good diuresis from the latter drug he continued to accumulate fluid so that by July 7, 1930, he was extremely waterlogged, weighed 246 lb and showed all the signs and symptoms of advanced congestive failure. Medical treatment had apparently failed.

Nevertheless the same measures were continued even more intensively and the results are shown below. For the next three weeks he was seen at home at frequent intervals and kept in bed. In addition to urea and digitalis he received five injections of salyrgan. When he returned to the clinic he had lost 21 lb and felt very comfortable.

From then on for over four years he has done remarkably. He has consumed approximately 300 lb of urea and attempts to discontinue it are invariably followed by gain in weight and dyspnea. Digitalis has easily controlled the ventricular rate. At first he was seen every week and received salyrgan at almost every visit. As he improved he was seen less frequently, and received fewer injections of salyrgan. This can readily be seen from the fact that in the last six months of 1930 he received salyrgan ten

times; in all of 1931 he received five injections; in 1932 he had four, and in 1933 only three injections were given. The last salyrgan was given June 12, 1933. When last seen (August, 1934), he was fairly comfortable and had no complaints. He was able to attend to the household duties for his wife, who is also an invalid, and he could walk from his home to the hospital, a distance of one-half mile up a steep hill. His weight was 202 lb., the lowest in almost five years, and beyond cyanosis and liver a hand's breadth below the costal border, there were no signs of circulatory failure. He was still taking urea and digitalis regularly.

SUMMARY

1. Ambulatory treatment has been applied to a series of cases of advanced cardiac insufficiency over a period of several years. These were individuals with long-standing congestive failure who had hitherto required numerous admissions to various hospitals. We were guided chiefly by observation of the weight, the degree of dyspnea, and the ventricular rate.

2. We found the chief problem to be the prevention and control of fluid accumulation which no longer yielded to digitalis alone. The treatment consists chiefly of the intensive and systematic use of diuretic measures. Restriction of fluid and salt intake is accomplished by specially calculated diets. The so-called "maintenance diuretics," urea or ammonium nitrate, are given constantly to help prevent reaccumulation of fluid. Frequent injections of a mercurial diuretic are used when rapid action is necessary. Digitalis and other drugs are administered when indicated. Through a special arrangement it is possible to treat the patient at his own home if he is temporarily unable to attend the clinic.

3. Our concept of the treatment of these

cases is similar to that in diabetes. The patient must be made to understand the object of each point in the treatment of his disease. Only in this way, with constant vigilance on the part of the physician, can we secure the utmost co-operation from the patient, which is probably the most important single factor in determining our success or failure.

4. The above methods can be successfully used in these individuals while they are ambulatory without any danger, and relatively long periods of well-being can be obtained. The fact that the patients are able to remain in their home surroundings has been of distinct psychological importance. At the same time, the hospital has been enabled to use its beds for a larger number of patients. It is by no means claimed that the improvement obtained in this way, renders the patients less liable to sudden death. Whether or not life has actually been prolonged, we are at present in no position to say. There is no doubt, however, that their existence is made much more tolerable to them.

5. The intensive ambulatory treatment with diuretic measures affords considerable relief for prolonged periods to the great number of cases which do not respond to the usual methods, including digitalis. It is suggested that it be given a more widespread trial.

AIR-STAMPS GAVE HIM AN AIR-RIDE

An American physician, Dr. W. E. Aughinbaugh, traveling in Italy, received a large packet of letters from home when he landed at Leghorn, and was amazed a little later, on his way to catch the train to Rome, to be accosted by two officials and taken back to the customs office on the pier. There the customs chief greeted him warmly, as the story runs in the *Chicago Tribune*, and said: "Señor, in looking over your letters this morning, I noticed many American air-mail stamps. My little boy is collecting stamps but he has none of the ones issued by the United States. It was my intention to ask for these stamps when you arrived but I missed you. Will you be good enough to cut them from your

envelope and give them to me for him?"

"Of course, it was impossible for me to refuse," relates Dr. Aughinbaugh. "Angrily I cut the stamps from the envelopes and handed them to him saying: 'You have kept me from going to Rome, where I had hoped to spend two days sightseeing before returning to the ship.'"

"That can be easily remedied," answered the official. 'I will have a Government airplane fly you to Rome from this city.' And that is why I was waiting at the station in Rome for the arrival of the train bearing my fellow passengers, who had looked upon me as having been arrested for some crime in Leghorn."

PHASES OF OTOLARYNGOLOGY OF INTEREST TO THE GENERAL PRACTITIONER

MARVIN F. JONES, M.D.

New York City

A paper describing procedures of practical value to the general practitioner is a difficult assignment. My first attempt resulted in the textbook type of discourse, detailing various diseases and a method of treatment. Analysis of my opus demonstrated the reason for its failure was that practically all the treatment advocated belonged in the realm of general medication. The list of remedies having only local value included nothing unusual, nothing particularly new, and certainly nothing that would stimulate the interest of the tired general practitioner.

At dinner preceding the joint meeting of the Pediatric and Otolaryngological Sections of the Academy there was a discussion in which the pediatricians asked questions which to me, an otolaryngologist, were astonishing. "Should a tonsil be removed?"—"What are the indications for removal?"—"Are patients benefited by removal?"—"What do you do for a common cold, if anything?"—"Does sinusitis ever become cured?"—"Of what value are operations on the sinuses?" These are a few samples.

There is a tendency to accept the answers to these questions with a smug complacency which eliminates them from the argumentative category.

If one were to tell what he does for the common cold, he would see that ordinarily most of the directions would consist of general medication, and that a general practitioner could apply the local remedies just as efficiently as a specialist. Why, then, do patients with colds come to a specialist's office?

In boom times, the physician who by good fortune had escaped the reputed golden lure of a specialty used his office as a bureau of information. If his patient complained of dysmenorrhea, that meant Dr. Brown; rhinorrhea meant Dr. Smith, and gonorrhea, Dr. Jones. The next time his patients needed attention, they were able to dispense with directions, because they had learned the road. When these patients used to arrive at a specialist's

office, they were asked what doctor referred them. Their answer would be Dr. So-and-So. Patients arrive now—occasionally—and when the request is made for the name of the doctor who referred them, the answer is that they were directed by the patient who was referred by his family doctor.

The specialist was created or grew to perfect himself especially in some chosen field. He should be used in consultation when a problem presents itself in general practice. The broader the field, and the more efficient in his realm the general practitioner becomes, the narrower the field and the more useful will be the work of the specialist.

If the family doctor would return to his old position as medical director for his patients, and personally administer to their medical needs, it would benefit all concerned. A consultation when needed should be a source of information and in the nature of postgraduate instruction for the doctor who takes advantage of the opportunity to be present at the examination. At the same time the family doctor would be able to estimate the ability of his consultant, and eventually his files would hold concrete answers to questions such as those listed earlier in this paper.

Dr. Murray Bass gave an illuminating and useful report on about 150 cases of tonsillecтомies which had occurred in his private practice. He knew why he wanted the tonsils removed, because his cases had been studied. He then took his patients to a competent specialist. He made sure that the operations were efficiently performed. He then noted the effect of the operation on the symptoms of which the patient had complained. He reported 88 per cent favorable results.

Impressions are misleading, and should rarely be voiced. When statements can be fortified by facts, they make valuable records.

Many questions have their answer in the records of the general practitioner. The specialist's contact with a patient is usually

times; in all of 1931 he received five injections; in 1932 he had four, and in 1933 only three injections were given. The last salyrgan was given June 12, 1933. When last seen (August, 1934), he was fairly comfortable and had no complaints. He was able to attend to the household duties for his wife, who is also an invalid, and he could walk from his home to the hospital, a distance of one-half mile up a steep hill. His weight was 202 lb., the lowest in almost five years, and beyond cyanosis and liver a hand's breadth below the costal border, there were no signs of circulatory failure. AIR-STAMPS GAVE HIM AN AIR-RIDE

An American physician, Dr. W. E. Aughinbaugh, traveling in Italy, received a large packet of letters from home when he landed at Leghorn, and was amazed a little later, on his way to catch the train to Rome, to be accosted by two officials and taken back to the customs office on the pier. There the customs chief greeted him warmly, as the story runs in the *Chicago Tribune*, and said: "Señor, in looking over your letters this morning, I noticed many American air-mail stamps. My little boy is collecting stamps but he has none of the ones issued by the United States. It was my intention to ask for these stamps when you arrived but I missed you. Will you be good enough to cut them from your

envelope and give them to me for him?"

"Of course, it was impossible for me to refuse," relates Dr. Aughinbaugh. "Angrily I cut the stamps from the envelopes and handed them to him saying: 'You have kept me from going to Rome, where I had hoped to spend two days sightseeing before returning to the ship.'

"That can be easily remedied," answered the official. 'I will have a Government airplane fly you to Rome from this city.' And that is why I was waiting at the station in Rome for the arrival of the train bearing my fellow passengers, who had looked upon me as having been arrested for some crime in Leghorn."

the health and comfort of the ailing multitudes who have a normal mentality."

The important items in local medication are aëration and adequate drainage. To produce these effects, I have used Adrenalin Inhalant. The old formula proved eminently satisfactory. Unfortunately, the new formula has been placed on the market under the same name. In four instances I have observed symptoms resembling adrenalin reactions following its use. An advantage of the old formula is its deterioration. It prevents the patient from using such a strong medication for a routine spray.

Whatever else the use of epinephrine and ephedrine preparations may do, they at least give the patient a sensation of local relief. Patients, strange to relate, appreciate a little relief. And doctors in their scientific enthusiasm are apt to overlook the fact. General medication is most important, but since there are individual preferences, I will not add my preference to the overloaded list.

CAN WE CURE SINUSITIS?

The answer is yes. Do we cure all cases of sinusitis? To this question the answer is no. It ought to be reiterated that until differentiation is made between allergic attacks and infective sinusitis there will be failure in both operative and therapeutic measures. There may be an allergic sinusitis without infection, there may be allergic sinusitis with infection, there may be an infected sinusitis in which the allergic cause has ceased, and there may be an infected sinus with no demonstrable allergic connection. Here again the diagnosis is essential before proper treatment can be instituted.

For my acute sinusitis patients, I order the following routine:

1. Take full glass citrate of magnesia before lunch.
2. Spray the nose every two hours with adrenalin inhalant spray (Parke Davis old formula). Use in a DeVilbiss atomizer.
3. Follow the nasal spray with the Tincture of Benzoin compound steam inhalation.
4. Take two five grain acetylsalicylic tablets every three hours with some food (saline crackers).
5. Drink at least one glass of fluid every half hour preferably fruit juices (lemonade, orange, or grape fruit juice or grape juice with enough sugar to suit taste).
6. Remain in bed.
7. Regular balanced diet.

8. Do not over-indulge in alcoholic drinks.
9. The room temperature should be around 70°, depending upon the humidity for variations.
10. Eliminate contacts with other people.
11. Avoid draughts.

When the patient religiously follows these directions, it rarely becomes necessary to operate on an acute sinusitis. If the original cause of the sinusitis has been allergic, and the patient again comes in contact with the special protein after a cure has been effected, a recurrence is to be expected.

Operations suffer in their results because of recurrent allergic attacks. Proper diagnosis of the underlying factors and intelligent selection of the correct procedure will diminish materially the repeated operations which have unfortunately been too common in rhinology.

One of the most common secondary manifestations of chronic sinusitis is a persistent cough. A prolonged cough may point to a possible sinusitis as the cause.

Pus in the nose or more particularly in the nasopharynx which is present over a protracted period, indicates sinusitis. Transillumination although not diagnostic of sinusitis is a valuable aid. More recently, I have tried fluoroscopy in diagnosis, and it has proven very satisfactory. In suspicious cases I resort to the radiogram. We must always keep in mind that a radiogram sometimes gives us an erroneous impression. It is used as an aid in diagnosis, but is not, of itself, sufficient.

COMMENT

In order to relieve patients of distressing symptoms, it is necessary to make an accurate diagnosis of the cause. It is equally necessary to select the proper therapeutic and operative procedures. (This statement sounds ridiculously trite but good results depend upon the literal observance of its text.)

Undiagnosed allergic manifestations in the upper respiratory tract probably ruin more good results from operations than poor operative technique.

The general practitioner should cultivate more intimate contacts with his consultant and learn by these contacts.

The final answers to most problems are to be found among the records and these records must be used to formulate accurate decisions.

brief, and he is often unaware of the final results. Though follow-up queries are possible a much more satisfactory estimate of a patient's condition may be obtained from the patient by the family doctor.

The questions of whether a tonsil should be removed has been answered in the most effective and conclusive way. When should a tonsil be removed? No tonsil should be removed before a thorough examination, both general and local, has been completed. Better end results would be obtained if this dictum were always followed. There is the common example of the patient who has complained of frequent attacks of "sore throat." Soreness of the throat quite commonly means tonsil trouble to the laity. After the tonsils are removed, the attacks of sore throat may continue. The operative procedure is condemned because the desired result was not obtained. Sinusitis was probably the primary cause of the soreness in the throat, and although a tonsillectomy sometimes helps to cure a sinusitis, it usually will fail.

The objective signs which I have considered important indications for removal of the tonsils are briefly stated:

1. Enlargement of the anterior chain of cervical lymph glands.
2. Recurrent attacks of tonsillitis.
3. Peritonsillar abscess.
4. Pus expressed from the tonsils by a tongue depressor or Hurd's suction tubes. (We all recognize in the last instance that caseous material need not be mistaken for pus.)
5. Recurrent colds of non-allergic origin.
6. Mechanical obstruction to the throat.

A type of case which offers a problem is that of the small buried tonsil without demonstrable infection. I have removed these tonsils as a possible focus for some general infection on the advice of the physician in charge of the patient. Rarely have I been chagrined by the absence of adequate pathology in this type of tonsil.

I prefer to remove tonsils during a period when upper respiratory infections are at a minimum if the situation permits. Tonsils removed in the late spring or early summer afford the patient the advantage of healthier months for convalescence. Sometimes it is advisable to allow only part of the summer for recuperation, but usually the convalescence from a prolonged illness is more rapid if diseased tonsils are removed.

Too little attention has been directed towards the adenoids. Though they deserve as much consideration as the tonsils, they receive little except as an object of routine removal. Even painstaking removal has been neglected. The results of adenoidectomy have been difficult to estimate because of their universal marriage to the tonsil in operative technic. Many doctors advocate the removal of adenoids without removing the tonsils. In some instances the operation on adenoids alone is justifiable, but generally speaking the procedure is inadequate. When the adenoid is removed it should be attended with the same skill as the tonsil. The operation should be done under sufficient general anesthesia to produce relaxation. The catch-as-catch-can method under insufficient anesthesia will not produce adequate results.

Do tonsils and adenoids recur following their surgical removal? Some practitioners will tell the patient that the tonsils and adenoids have "grown back." Rarely do we see the regrowth of a tonsil. The adenoid is more prone to regrowth following an adequate removal. Should the adenoid tissue again become hypertrophied after removal, a thorough investigation of the sinuses will frequently disclose an irritating postnasal discharge.

THE COMMON COLD

Until differentiation between upper respiratory infections and allergic attacks is learned, treatments of the common cold will remain unsatisfactory. Allergic attacks are not limited to the seasonal variety, but may occur at any time during the year or be intermittent during the year. In addition, these allergic attacks are the results of ingested foods as well as inhalants. They produce not only the acute attacks which are easily recognized, but also the sub-acute and chronic symptoms with nasal pathology.

In upper respiratory infections, nearly every one has his pet procedure. A recent publication calls attention to the opiates and their derivatives. It again serves to remind one not only of the sedative effect, but also of the medicinal values of these therapeutic agents. The forbidden heroin with terpin hydrate has never been replaced as a cure for the torturing dry cough. Just another example of the old story: "Legislation for the mentally inadequate few which affects

(85 per cent) This is a credit to the practicing physicians and the community Department of Health The Schuck test as a check on the success of diphtheria immunization had been used very little, (12 per cent) and thus almost wholly among the private patients There is no free clinic in the City where Schuck testing is done

Correction of undesirable habits and behavior of these children are considered important Those who are not under the care of their private physicians will be followed up in the Behavior Clinic of the New Rochelle Hospital

COMMENT

It is felt that such a campaign for the examination of children of this age is a very valuable public health measure Many conditions are brought to the attention of the parent, which, given proper care, will be helpful in the child's development and good health The establishment of the habit of an annual health examination, begun in childhood and carried through adult years, will be of value to the general health of the community Much loss of school time is prevented by making this examination sufficiently long before the child enters school

By registration of the children in three different groups, according to their economic status, private physicians participate

to a greater extent in this preventive health work.

The combined effort of the local physicians with the Parent Teacher Association when assisted by the Health Department and Fire Department makes it possible to reach and examine large numbers of children.

CONCLUSIONS

1. The number of children from 2 to 5 years of age found needing medical attention was very large (99.5 per cent).

2. Schick testing had been done very infrequently as a check on diphtheria immunity (12 per cent).

3. There was a low percentage of positive tuberculin tests (3 per cent).

4. Large numbers of children with knock knees and weak feet were found (22 per cent).

5. Many behavior abnormalities were found (9.5 per cent).

6. This type of examination is a valuable public health measure.

CASE REPORT

PROPHYLACTIC TREATMENT IN RABIES

SAMUEL L. ELLENBERG, M.D.

New York City

ABSTRACT

A case of rabies is reported because of the failure of the standard methods of prophylactic treatment in this case and to record the spinal fluid findings.

On July 11, 1934, a 7-year-old boy, J. K., was admitted to the Surgical Division of the Children's Ward of Lincoln Hospital because of an extensive laceration of the right lower eyelid and numerous small bites of the face which were inflicted by a pet dog while the child was asleep. The dog had been in good health but after inflicting the wounds he began to froth and chewed at the door.

Except for the lacerations of the eyelid and of the face the physical examination was essentially negative. There were multiple lacerated wounds of the lower right eyelid, one wound going downwards and laterally from the inner canthus for about $1\frac{1}{2}$ inches causing the lower lid to hang downwards only by its lateral attachments. The other wounds were not so extensive but cut the lid into ribbon-like strips. The lacrymal duct was severed. There was no injury to the eye. There were numerous small bite wounds scattered over the face and beneath the chin.

The wounds about the eye were cleansed with boric acid. This was followed by 20 per cent argyrol which was also dropped into the eye. The wounds were carefully closed with interrupted dermal sutures. The remaining wounds were cauterized with nitric acid followed by aromatic spirits of ammonia.

The following day the dog was reported rabid and antirabic treatment was immediately instituted—a lapse of 36 hours after the infliction of the bite. At first the Department of Health sent up a batch of 14

vials of vaccine prepared according to Semple's method, but when informed that the bite was severe and dangerously near the optic nerve, the Department advised that double the usual dosage should be given instead of the customary 14-21 injections of 2 c.c. of vaccine. Consequently daily injections were given subcutaneously for 15 days, beginning with 2 c.c. and rapidly increasing to 4 c.c. of the vaccine on the third day, where it was held until a total of 57 c.c. was administered.

The child's course in the hospital was uneventful. The wounds were kept clean and healed satisfactorily. At time of discharge from hospital, July 29, 1934 (18 days after admission), a note stated the child was in good general condition and there were no manifestations of rabies.

On August 7, 1934, the patient was readmitted to hospital. Since discharge the child had been well up to 4:00 A. M. on August 5, 1934 (25 days after dog bite), when he woke up complaining of pain in the right ear which persisted to time of admission, except for a slight remission following syringing. He began to vomit about every half hour and could hold no food down. On August 6, 1934, the vomitus became slightly blood-stained and that afternoon a right-sided paralysis of the face was noted. On morning of admission, at home, patient was delirious and developed some difficulty in speech.

Examination of the child on the ward showed he was co-operative, oriented, understood all questions but appeared unable to answer them. Speech was jerky and hoarse, and there was some mild difficulty in swallowing. He appeared quite thirsty, showed

some foamy saliva at the mouth. The left pupil was greater than the right but both reacted to light and accommodation. There was a reddening of the right eardrum. The pharynx was infected and full of mucus, and there was a weakness of the swallowing muscles and a palatal paralysis. The tongue protruded to the right. Slight facial paralysis was present on the right but no stiffness, Kernig, Brudzinski nor Babinski. Lungs, rhonchi present—no other changes. Heart, negative. T, 104, P., 110; R, 24. Laboratory data: Urinalysis showed Albumen +, Sugar +, Acetone +, and a number of leukocytes.

Spinal tap revealed clear fluid under normal pressure—80 cells—mostly lymphocytes, globulin = 0, Sugar, normal.

A member of the Meningitis Division of the Department of Health was called into consultation and his opinion was that the patient had either a high bulbar polio or rabies.

Later that day the child had definite difficulty in swallowing, fluids were regurgitated, and he developed a weak cough which did not appear capable of expelling the fluids from the respiratory passages and upon examination a laryngeal and soft palatal paralysis were found.

With the progress of time the patient continued to be alert but restless, fully cooperative but could not protrude the tongue. Cyanosis of lips became marked and a mild erythema of the face, forearms, and arms developed. Cyanosis and mental clarity continued till the exitus, which came on suddenly that same evening (August 7, 1934).

An autopsy was performed by the medical examiner who reported. "A well developed and nourished male with cyanosis of lips, ears, fingernails. Healed scar at inner side of

right upper lid. Basilar subarachnoid hemorrhage (15 c.c. of blood). Blood vessels of brain and dura congested. Bases of lungs congested. Heart dilated, otherwise normal. Gastro-intestinal system congested. Pancreas congested. Kidney markings congested. Anatomical diagnosis: basilar subarachnoid hemorrhage; general visceral congestion, rabies. Microscopic stain for Negri bodies of Purkinje cells of cerebellum positive and same corroborated by the Department of Health."

COMMENT

This patient developed rabies 10 days after the last injection which would indicate a marked susceptibility of the child or a marked intensity of the infecting virus or a failure on the part of the child to manufacture protective antibodies. It is generally considered that at least 14 days must lapse after the completion of the treatment before immunity is attained. In 95 per cent of the cases treated this immunity is attained but there still remains a group in which the present case can be included that apparently requires a more potent vaccine than is available at the present time.

The various systems of medicine and other medical textbooks do not mention anything regarding spinal fluid findings in rabies. In looking over the case reports in the literature it is curious that in only a small percentage was a spinal tap performed and very few recorded the spinal fluid findings. The spinal fluid report in this case appears to agree with those findings recorded in the literature, viz, a clear, colorless fluid normal or under slightly increased pressure, increased number of cells, mostly lymphocytes, normal sugar, normal or decreased globulin.

Health Insurance at Its Worst

At its best compulsory health insurance is an undesirable expedient that places a heavy economic burden upon the working classes in return for second rate medical care. At its worst it is a vicious political device that lowers wages to support an intricate bureaucracy and suffocates medical initiative beneath a mass of red tape. The Byrne bill (Sen. Int. No. 474) is a bad sample of this type of legislation. Even those who believe in obligatory prepayment for illness must find much in it to criticize.

In every nation where sickness insurance has been tried, in every country where it has been studied, there is agreement on the need to deal separately with cash and medical relief. The Byrne Act combines these benefits in defiance of all experience and precept. Ignoring actual needs and the precarious financial condition of government and industry, it sets the upper limit of wage eligibility at sixty dollars a week, draining business and the taxpayer to provide medical service for thousands who are well able to provide for themselves.

The administrative set-up described in the Byrne bill should open the eyes of those who believe that compulsory health

insurance would lower the costs of medical care. At the top is the Health Insurance Board, consisting of a ten-thousand-dollar-a-year Director and three other members, each of whom would receive an annual salary of seventy-five hundred dollars plus traveling costs and incidental outlays. A State General Advisory Council of twelve and a State Medical Advisory Council of nine would also be permitted expense accounts. In an unspecified number of districts, offices would be set up, each headed by a full-time finance and a full-time medical supervisor. These districts would be subdivided into local areas, each with its own full-time finance and medical managers. Aiding the local offices would be local councils, the members thereof receiving per diem fees in addition to traveling expenses. These councils, in turn, would be assisted by an unlimited number of local advisory committees, also entitled to draw incidental costs. For this involved bureaucracy (and only a meager skeleton has been sketched), the worker would pay in periodic deductions from his pay, in lowered wages and augmented living costs and in increased taxation.

Senator Byrne, who is very specific in other respects, fails to state what the doctor's compensation would be under his proposal. Local areas are left free to choose among flat salaries, a per capita system of payment and the fee-per-treatment method—but the question of amounts is left in darkness.

In view of the fact that the Federal government, after months of study, has seen fit to eschew the dubious benefits of compulsory health insurance, there is little warrant for the state to rush precipitately into this controversial system. The Byrne bill is especially obnoxious since it embodies features that are condemned even by the proponents of obligatory pre-payment. It is not enough to beat this act; it must be beaten so crushingly that it will not raise its head again. The profession should rally all of its forces to defeat a measure that would lower the American standard of living, substitute quantity for quality in medical care and make the physician the ill-paid underling of an oppressive bureaucracy.

Invoking the Bogeyman

In New York City, there exists an organization called the Association of Private Hospitals, Inc. This association was organized originally to improve conditions in the private hospitals, and serve the interests of their loosely affiliated staffs. They publish an official organ.

We should welcome their laudable endeavor when they confine themselves to their natural objectives. When they go afield however, and circularize many of the States' physicians with an editorial, entitled "Medical Profession Endangered by Proposed Vicious Legislation," we cannot let the factual inaccuracies go unnoticed. On the other hand, we need not take them too seriously.

The spectres conjured up by the *New York Physician* in its January issue will not terrify those who pause to think before they flee. The bill which has produced such violent editorial jitters in our contemporary restores the free choice of physician to the injured employee. To prevent abuses which might militate against this provision, the profession is asked to assume responsibility for the competence and integrity of its members. Any qualified practitioner may have his name placed on the approved panel to be drawn up by the county societies, provided that he agrees to limit himself to the fields for which he is trained. An otologist, for example, would not be authorized to treat genito-urinary disturbances. Neither would an obstetrician be accepted for lung surgery. Such restrictions are entirely reasonable and do not threaten the professional liberty of the well-intentioned physician in any way.

As the statutes now stand, a medical man cannot treat an industrial injury with any hope of being paid under the Workmen's Compensation Law unless he has received specific authorization from the employer or (in the majority of cases) the insurance company. Through the persistent efforts of the State and County medical societies (the bogeymen of *The New York Physician's* editorial), the principle of free choice has begun to receive favorable consideration.

The Legislature and Labor Department

insist, however, on some guarantee of medical competence in this type of case. While the State and County societies may not represent the entire profession, they unquestionably represent the greater part of it. Certainly there is no other body that speaks more authoritatively for the mass of physicians; and the State does no more than recognize an existing fact when it places upon organized medicine the duty of drawing up a panel of doctors for industrial cases.

Any talk of sinister attempts to give the State and County medical societies autocratic control over the profession, with power to disenfranchise practitioners whose looks or personality do not please, is absurd. The officers of these organizations are elected annually by the members. There is no permanent hierarchy that stands to benefit from the responsibilities which the State seeks to impose on organized medicine.

The profession must face the fact that the State will not consent to the free choice of physicians in workmen's compensation cases unless some responsible medical organization serves as guarantor of the honesty and ability of practitioners working in this field. If it does not consent to some form of self-regulation, the alternatives will probably be State control or a continuance of present conditions under which the carriers call the tune. Instead of invoking fantastic bogeymen, minority medical groups should weigh the real dangers that threaten their professional rights.

Sterilization as a Eugenic Method

In the course of a series of lectures delivered in Bremen on "The Prevention of Useless Lives" and reported by the Berlin correspondent of the *Journal of the American Medical Association* one by F. K. Walter¹ is of particularly timely interest. Walter points out some of the difficulties inherent in applying the Mendelian laws to human breeding. Coming, as this lecture does, from a country where opinion on these topics is exceedingly biased, one may repeat what Johnson said of the dog that walked on its hind legs. "The wonder

¹ Berlin Letter. *J. A.M.A.* 104: 412, 1935.

lies not that he does it well, because he doesn't, but that he attempts it at all." The problem is really vastly more complex than would appear from the reported account of Walter's lecture.

Recent research in England (Hurst)² shows that all forms of mental deficiency are recessive to normal intelligence (in other words they may appear in offspring of normal parents). In 93 subnormal families, 103 mentally deficient parents produced 338 offspring, of whom 110 were mentally deficient. In the normal families, 626 normal parents produced 1,032 offspring, of whom 86 were mentally deficient. If the German law had been applied and all mental defectives sterilized, 110 mentally deficient persons would have been spared the community of 1,370 persons. Eighty-six mentally defective persons, the offspring of normal parents, would, however, continue to grace the populace. The birth of 228 normal persons would have been prevented; of whom 78 were distinctly supernormal, and some of whom reached definitely into the borders of authentic genius.

All criteria for sterilization seem to fall down on rigid inspection. Some of those proposed by the present German law do not become apparent till an age is reached when people have long married and had their families. Even if we take the one which often becomes apparent in childhood, epilepsy, we must admit that half the cases are not truly hereditary. Those cases which are definitely hereditary can in no manner be prevented, because epilepsy is recessive and, as time goes on, the rate at which it disappears becomes slower and slower because the laws of chance operate to lessen the possibility of the meeting of the genes.

In a community without selective mating in which 1 per cent of the population was affected with a simple recessive degenerative condition such as epilepsy, and provided all these individuals were sterilized, it would require four generations to reduce the incidence to 0.5 per cent; seven generations to 0.25 per cent. If the disease

occurred with a frequency of 1 pro mil, it would take 13 generations to reduce the incidence to half of the original value. Hence were measures similar in nature to those proposed by the present German government put in force by Charlemagne, the chances of the birth of the "mental defective" epileptic Napoleon would scarcely have been halved.

Serological Diagnosis of Brain Tumor

It is a mathematical truism that we must have as many equations as we have unknown quantities if we are to get any fixed value for the unknowns. If in the course of a scientific investigation it becomes necessary to fix the conditions of our variables, it is very advantageous to borrow the technic of another science, which by an indirect method will give us the missing equation. This is beautifully illustrated in the astronomical data furnished by investigation of the chemical nature of the atmospheres surrounding the various planets.

In clinical medicine, where we are dealing with so many variables, the methods of all sciences must be adapted to furnish exact data. The investigations of Reicher¹ on the serological characteristics of various tissues affords a striking example. Uhlenluth first found organ specific cell elements in the lens of the eye. Attempts to obtain antisera from other organs have been futile up to very recently. With finer technic, based on the known differences in embryological origin of the various parts of the brain, Reicher was able to distinguish between the anterior and posterior parts of the hypophysis by the use of specific antisera. By preparatory treatment of a rabbit with posterior lobe substance, specific antisera were formed which reacted with posterior lobe or brain extracts but never with anterior lobe. He was finally able to prepare extracts which reacted with posterior lobe substance, and produced scarcely any with brain substance. This confirmed the previously postulated theory of the ontogenetic double

² Hurst, C. C., International Congress of Anthropological and Ethnological Sciences, London, 1935.

¹ Reicher, H., *Zeit. f. Immunitätsforsch.* 80: 85, 1933.

origin of the hypophysis. He was then able to show that the medulla and cortex of the adrenal gland similarly could be differentiated.

The strong reactive power of organ specific brain antisera with an alcoholic adrenal medulla extract showed a biological affiliation with the nervous system. Carrying the idea still further, it was shown that an infiltrating neoplasm of the brain, a glioma, could be demonstrated by a serological reaction. By preparatory treatment of a rabbit with cooked tumor tissue, antisera are formed which, in properly chosen dilution, react with homologous tissue extracts without reacting on the tissue of the same brain or on the control extracts. The development of this principle with further refinements of technique must certainly, in the near future, be of inestimable value in the diagnosis of various tumor growths.

Newer Concepts of Shock

Based upon careful experimental observation Parsons and Phemister¹ present an excellent physiological explanation of surgical shock which remains unresponsive to either infusion or transfusion of blood. By maintaining the blood pressure at a low ebb for several hours in dogs, these observers were able to show that in spite of all subsequent treatments the animals failed to survive because of irreparable damage to the tissues from the sustained low blood tension. Postmortem examination revealed capillary congestion, hemorrhage and moderate necrosis of some of the tissues. Additional findings were free blood in the lumen of the intestinal tract and increased concentration of the blood cells.

Within the last few years the conception heretofore held of the pathogenesis of shock has undergone revision and change.² Certainly considerable discredit is thrown upon the influence of "a histamine substance," as an integral etiological factor in

shock. Blalock³ has shown, for example, that traumatic injury of large masses of muscles of an extremity results in a dilatation of the small blood vessels of the tissues. It is the local diapedesis, loss of fluid and blood plasma at the site of injury which is responsible for shock.⁴ The difference in weight of the traumatized extremity as compared to the normal one, points to the loss of fluids into the tissues as the direct cause of the decreased circulatory volume. Obviously, such a combination of circumstances will produce a concentrated blood. On the other hand, if shock is produced by acute blood loss, there is a dilution of the plasma since fluids must enter from the tissues in an endeavor to maintain the blood volume.

This newer concept of traumatic shock bears out many empirical observations. The efficiency of adequate splintage of a traumatized extremity so as to minimize capillary dilatation, the necessity for increasing the circulating blood volume are comprehended. The futility of employing temporary vasoconstrictors becomes apparent. In reality they decrease rather than increase the blood supply to the organs.

The effects of sustained hypotension associated with shock have been substantiated by clinical observations. Beard, Wilson and Weinstein have shown that when shock has existed for many hours infusion of salt and of glucose are practically valueless,⁵ for not only is there loss of the greater part of the fluid administered, but there is also observed a depletion of the protein content of the plasma when whole blood is injected. On the other hand, there is no decrease in the protein content of the blood because protein has been injected. In protracted shock all measures fail. Therapy resolves itself into early recognition, blood transfusions, warmth and proper splintage of the traumatized tissues.

Society Activities

Committee on Legislation

BULLETIN NO. 4, FEBRUARY 4, 1935

The following bills have been introduced since the issuance of our last bulletin:

Senate Int. 447, Feinberg; Assembly Int. 578, Heck, amends the Workmen's Compensation Law so as to create an insolvent carriers fund. Referred to the Labor Committee in the Senate and the Ways and Means Committee in the Assembly.

This is an attempt to produce a substitute for bills Senate Int. 18 and Assembly Int. 18. The principal argument advanced at the hearing by the proponents of the State Fund bill was that bankruptcy of certain companies had left many injured workmen without deserved compensation. Mr. Feinberg suggests that commercial companies create a guarantee fund to prevent a repetition of such default.

Senate Int. 474, Byrne; Assembly Int. 718, Byrnes, enacts the Health Insurance Law, for establishment and administration of a system of health insurance, employer to pay into fund amounts ranging from $3\frac{1}{2}$ to $1\frac{1}{2}$ per cent of total wages, based on weekly wage rate, employee to pay from 1 to 3 per cent of his wages according to weekly rate, and State to pay $1\frac{1}{2}$ per cent of total of wages paid by employers, and appropriating \$100,000. Referred to the Insurance Committee in the Senate and the Ways and Means Committee in the Assembly.

[This bill is the subject of an editorial in this issue.]

Senate Int. 492, Schwartzwald, amends the Public Health Law relative to general powers and duties of local health boards and to treatment required for venereal diseases in certain cases. Referred to the Health Committee.

Deletes from the law requirements regarding the manner in which boards of health of local communities shall provide treatment and substitutes, instead, that this treatment shall be provided in accordance with rules and regulations of the sanitary code.

Senate Int. 505, Kleinfeld, adds new section to the Mental Hygiene Law for certification of qualified psychiatrists by a board of examiners in Mental Hygiene Department. Referred to the Health Committee.

Senate Int. 506, Kleinfeld, amends the Criminal Code for appointment by court of commission of three persons, one to be an attorney, one a qualified psychiatrist, to determine sanity of defendant or for commitment of defendant to a public hospital for

observation, and making other changes. Referred to the Codes Committee.

These are the two bills which we have followed for several years, which would create a board of qualified psychiatrists for assistance to the courts in determining the mental status of defendants, and providing for the use of such board. We have approved this set-up in past years and the conference the other day voted its approval of the present bills.

ACTION ON BILLS

Assembly Int. 321, Doyle, relative to withdrawal of a city from a county health district, etc., has reached third reading.

HEARINGS

Feb. 20 — Assem. 558	{ Sullivan, working hours of nurses in public hospitals; hearing before Assembly Committee on Labor and Industry.
Feb. 26 — Assem. 202	{ Farenga, applicants for civil service examinations; hearing before Assembly Committee on Judiciary.

CONFERENCE OF COUNTY LEGISLATIVE COMMITTEE CHAIRMEN

The conference of county chairmen held in Albany on Thursday, January 31, was without doubt the most successful conference we have had in recent years. The following thirty-three County Societies were represented: Albany, Allegany, Bronx, Broome, Cayuga, Chautauqua, Clinton, Columbia, Cortland, Delaware, Erie, Essex, Genesee, Greene, Jefferson, Kings, Madison, Monroe, Nassau, New York, Ontario, Orange, Otsego, Queens, Rensselaer, Richmond, Schenectady, Steuben, Suffolk, Tompkins, Ulster, Warren, and Westchester. There were also present all of the members of the State Legislative Committee and the following guests: Drs. Arthur J. Bedell, President of the State Society; Peter Irving, James N. Vander Veer, Frederic C. Conway, John J. Morton, R. P. Harris, Charles A. Earl, A. J. Hambrook, Jacob L. Moreno, Mr. Dwight Anderson, and Mr. J. Louis Neff.

The conference convened at ten o'clock. Dr. Aranow announced that the order of business would be to review the bills that had already been introduced, and asked Dr. Lawrence to lead in the review. Bills 18, 19, and 20 received considerable discussion. Unanimity in opposing 18 and 20 as drafted was immediately expressed, and unanimous approval of No. 19 was voted. Special pains were taken to discuss the provisions of No. 19 in order that every member of the conference might be particularly conversant with what the law will be if the bill is enacted. The representatives of several County Societies reported that their Societies had taken adverse action on the bill because of certain features, and principal among these was the responsibility that would be placed upon the County Societies. The argument was advanced that the County Societies are not sufficiently organized to administer the responsibility that would be placed upon them and that some provisions of the bill would favor political interference with the treatment of compensation cases. These were widely discussed and effectively answered.

Dr. Aranow encouraged the discussion with the hope that the conference could take unanimous action; he deplored the fact that one or two County Societies had taken their opposition to their legislators without regard to what the action of the majority of the County Societies might be. He appealed to the representatives that if ever there was a time when organized medicine needed to act as a unit, it is now, and that the wish of the majority should become the will of the Society; that those who are endeavoring to overthrow our present system of the practice of medicine are doing their utmost to divide our organization into small independent units.

Dr. Bedell was present during the entire conference and announced that the Committee on Trends had developed a program of publicity through which the State Society expects to assist the County Societies in informing the public on organized medicine's views with regard to the many propositions for socialized medicine which are appearing daily. At the close of the conference Dr. Rooney, a member of the Committee on Legislation and also chairman of the Committee on Trends, introduced Mr. Dwight Anderson as the director of the new publicity program. Mr. Anderson announced that he had with him Dr. Moreno, who had practiced for a number of years under the health insurance act of Austria. Dr. Moreno gave the conference a very graphic description of the ill effects of health insurance upon the public and the profession.

Action taken by the conference on the bills follows:

APPROVED

- Senate Int. 19—medical abuses bill
- Senate Int. 77—civil service examinations
- Senate Int. 123—carrier's physician, examination
- Senate Int. 154—reports of communicable diseases
- Senate Int. 208—lien bill
- Senate Int. 270—employment of dentists and health nurses
- Senate Int. 300—bovine animals infected with Bangs disease
- Senate Int. 312 and Senate Int. 314—blood-grouping tests
- Senate Int. 315—supervision of clinical laboratories
- Senate Int. 357—sale of lye and other caustic substances. (Dr. Bedell, speaking as a member of the Academy of Ophthalmology and Otolaryngology, urged that this bill be approved.)
- Senate Int. 365—civil service examinations
- Senate Int. 401—sale of drugs, etc., for prevention of venereal diseases
- Senate Int. 409—parking space in front of physician's residence
- Assembly Int. 321—withdrawal of city from county health district
- Assembly Int. 371—lien law (physicians only)
- Assembly Int. 372—members of Public Health Council
- Assembly Int. 461—clinical laboratories (including x-ray)
- Senate Int. 505—certification of qualified psychiatrists
- Senate Int. 506—examination of defendant to determine mental condition
- Senate Int. 514—hospital care of sick and disabled persons
- Assembly Int. 656—recovery for cost of relief

DISAPPROVED

- Senate Int. 18—State Fund, insurance
- Senate Int. 20—blanket occupational disease bill
- Senate Int. 302—health commissioner, bequests, hospitals
- Senate Int. 474—health insurance
- Assembly Int. 559—public welfare districts, free medical care

NO ACTION

- Senate Int. 1—unemployment insurance fund
- Senate Int. 44—free milk for undernourished children, etc.
- Senate Int. 45—county government, reorganization
- Senate Int. 60—county government, reorganization
- Senate Int. 67—old age relief
- Senate Int. 98—unemployment reserve fund

Senate Int. 118—car-fares and eyeglasses for indigent children
 Senate Int. 203—investigation of illegal practice of professions
 Senate Int. 246—TERA, transferring to Social Welfare Department
 Senate Int. 271—protection of water supplies
 Senate Int. 447—insolvent carriers' fund
 Senate Int. 513—debts, moratorium
 Assembly Int. 59—old age relief
 Assembly Int. 344—old age relief
 Assembly Int. 452—old age relief

Assembly Int. 558—working hours nurses, public hospitals
 Assembly Int. 644—workmen's compensation, silicosis, etc. (Approved in principle, but action deferred until later bill is introduced.)

Medical Broadcasts

Scheduled under the auspices of the Medical Information Bureau of the New York Academy of Medicine and the Medical Society of the County of New York from Station WABC, Columbia Broadcasting System:

Thursday, February 21, at 11:15 A.M., 15 minutes.

Subject: "The Old Family Doctor."
 Speaker: Dr. William F. Snow, General Director, American Social Hygiene Association.

Thursday, February 28, at 11:15 A.M., 15 minutes.
 Subject: "Face Maternity Well Informed."
 Speaker: Dr. George W. Kosmak, Secretary of the Obstetric Advisory Council, New York City Department of Health.

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked "private." All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.]

The New York Society of A.M.A. Approved Roentgenologists

January 23, 1935

To the Editor:

Those radiologists of the Greater Metropolitan District of New York who have been recognized as specialists by the American Medical Association, have formed a society known as the New York Society of A.M.A. Approved Roentgenologists.

The objectives of this Society are: (1) To promote a more cordial relationship between the radiologists and the other members of the medical profession, and to aid in the better understanding of each other's problems.

(2) To arouse among physicians that sense of professional ethics and loyalty, which apparently has been completely forgotten or lies dormant in many quarters, as evidenced by the fact that lay-owned and lay-controlled so-called "x-ray laboratories" continue to exist and flourish, while many well trained and ethical roentgenologists find themselves in great economic difficulty.

(3) To fight the evil of lay encroachment upon the practice of medicine. The ease with which laymen and lay corporations, although not licensed to practice medicine, manage to find ways of worming their way into the practice of medicine is a very serious problem which should be the concern not only of the radiologist but of all the other members of the medical profession. Lay organizations

are daily making deeper inroads into the practice of medicine, and the end is not in sight.

The New York Society of A.M.A. Approved Roentgenologists welcomes the moral support of the entire medical profession. It is evident, however, that the success of our efforts is dependent upon the active support of the entire radiologic body of the State. In the Greater Metropolitan District of New York, 97 per cent of the A.M.A. approved roentgenologists have already become members of the Society. Encouraged by the great local interest in the activities of the Society, the constitution of the Society was recently amended to enable all of the A.M.A. approved radiologists of the State of New York to become members.

The New York Society of A.M.A. Approved Roentgenologists wishes to take this opportunity of earnestly requesting all of the approved radiologists of the State of New York to apply for membership in the Society. Application should be sent to Dr. J. J. Master-son, 401 76th Street, Brooklyn, Chairman of the Membership Committee.

S. FINEMAN, M.D., *Chairman*
 W. H. BOONE, M.D.
 DAVID E. ERLICH, M.D.

Committee on Education

Current Comment

Income Tax Deductions for Professional Expenses

A professional man, in estimating the amount of income tax he is to pay, may deduct all necessary expenses incurred in the pursuit of his profession. These include the cost of supplies used in his practice, office rent, cost of light, water, fuel, and telephone in his office, the hire of office assistants, and expenses paid in the operation and repair of an automobile, based upon the proportion of time it is used in making professional calls or for other professional purposes.

Many physicians use their residences both as their offices and their homes. In such instance the physician may deduct as a business expense the rental value of the rooms occupied for office purposes if he actually pays rent, and also the cost of light and heat furnished these rooms. Also, he may deduct a portion of the wages paid domestic servants whose time is partly occupied in caring for these rooms. Membership dues in professional societies are deductible. Physicians and dentists who keep in their waiting rooms current magazines and newspapers for the benefit of their patients may deduct this item as a business expense. The cost of professional journals for the taxpayer's own use is also a deductible item.

The cost of technical books is not a deductible item, being a capital expenditure, but a proportionate amount for each year's depreciation of the books may be deducted. Depreciation may also be taken on office furniture and equipment. Insurance premiums on office or other professional equipment and liability insurance may be deducted. Automobile liability insurance may be deducted only when the automobile is used wholly in pursuit of the taxpayer's profession, and the cost of the entire upkeep may legitimately be claimed as a professional expense.

Girls' School Head Flays Health Insurance

Dr Jacob L. Moreno, Director of Research, New York State Training School for Girls at Hudson, New York, did a service on January 31 at the meeting of the Legislative Committee when he stigmatized the health insurance bill pending before the State Legislature as a measure under which patients would get poor medical care and physicians would degenerate into callous machines. Health Insurance cheats both the patient and the doctor. In the name of trying to advance

human welfare, such measures actually retard progress.

Dr. Moreno said, "I know from experience with actual reality that no matter how rosy the picture of ideal care for the poor that is presented by such schemes for health insurance in practice they do not work. They cannot work, because they fail to take account of factors in human relations which are indispensable to the practice of the healing art.

"No physician," added Dr. Moreno, "is capable of properly treating the large number of patients sent him under health insurance. So he is forced to evolve some mass production plan of operating his office to run people through his mill as fast as possible. A quick look, a stock prescription, a pat on the back, and out the door.

"The 'rush' system of handling patients is inevitable. When the technique of getting them in and out fast enough is perfected the doctor begins to lose that intangible 'something' which is vital to both himself and his patient—his morale. I do not know any doctor who remained long at this sort of practice in Austria who did not become hardened. A doctor's personal interest in his patient is essential. The response he makes emotionally to the trust reposed in him is important. If the patient comes to the doctor because of confidence in him and not merely because he is an insurance doctor, interest and insight are quickened. Mutual free choice is basic to good medical care.

Every person's capacity to expand emotionally, and to sustain a confidential relationship is limited. A physician may be able to maintain a keen mental activity while examining a few cases a day, but after his limit is reached the power to sustain the faculties on a high plane wanes until finally, when the last case of a long line is reached, the patient becomes merely a serial number on a piece of paper. Health insurance forces on the doctor an utterly impossible human task—to sustain a genuine personal interest in all the individuals of a miscellaneous crowd at his door.

"The insurance doctor does the best he can, but patients suspect they would get better attention if they came to him during his private office hours when he could give them more time. This is a distinct and definite injury to the character of the physician. He must hurry through his insurance patients so that he can have plenty of his best self left to take care of his private patients. This is a corrupting influence. He knows he has not lived up to the highest

tenets of his profession to give his best to every patient who comes to him. He has been forced by circumstances enacted by a law to do less than his best by some of his patients, and even his best with the few who see him privately gradually becomes not so good as it once was.

"Nobody who has not seen such schemes in practice as I have can realize how odious they are. They destroy everything that makes the healing art effective. A new face comes between the doctor and the patient, that of an inspector or supervising physician, or an insurance bureau bookkeeper, questioning on this and on that particular without the intimate understanding derived from having seen and known the patient. At best, the real patient, the one for whom the mass-production doctor is working, whom he must please if he is to live, is not the sick man, but an adding machine in the office of a bureaucrat who pays the fees out of an insurance fund. This man doesn't care whether the patient lives or dies, only how much he costs the fund. And his influence is exerted only in the direction of economy and other externals.

"Supervisors are needed in health insurance organizations. A controller or supervisor who brings in many complaints against doctors is a good supervisor—he is headed for promotion because medical practice has now become a business instead of a profession. Thus do we destroy a truly healing relationship of which trust and confidence is the basis, and substitute a chain-store, cut-rate imitation, which corrodes curative values needed to heal the sick.

"The system which we now have in the United States is not perfect. But I know from personal experience that the conditions imposed by health insurance are far worse. Health insurance is a type of socialized medicine. It is impossible to socialize the doctor unless the business man, the banker, and the lawyer are socialized, too. Until the time comes, if it ever does come, when we have communism or some form of collectivism, health insurance simply will not work. Though it applies only to the lower income groups, those groups will always feel they are getting less than they ought to get, even if the doctors are men of quality having lucrative private practices in addition to their insurance patients. Like all halfway measures, it will fail, despite the well-meaning altruism of those who sponsor such legislation. They do not realize, as the physician does who has practiced under such a system, how destructive it is to quality in medical care.

"Letters which have come to me recently from former patients in Austria state that conditions are no better now than when I

left five years ago, but are worse, if anything."

Compensation for Court Testimony

The Westchester Medical Bulletin for February makes the worth-while suggestion that physicians, when called upon to testify in a case in which they knew before appearing that their testimony will be of an expert nature, to make a practice of asking reasonable compensation for such services before they appear in court.

Lauds Organized Medicine

The Milwaukee Tissue says: "We wish to remind skeptics that no matter what difficulties they labor under at the present they would be infinitely worse were it not for organized medicine."

Physicians' Trade Union in Germany

The American Medical Association Bulletin for January, 1935, commenting on the one hand on the action of 6,000 physician members joining a Trade Union, and on the other hand upon harsh restrictive regulations in Germany including a prohibition to German physicians to send patients to the Marienhospital in Düsseldorf, asks: "What does it signify? The movement for the socialization of medicine has progressed far in England and farther in Germany. Can it be that the affiliation of several thousand physicians with a trade union in one country and the subjection of insurance physicians to harsh, dictatorial decrees in another country are developments that naturally attend on the establishment and operation of a system of socialized medicine?"

Low Wages a Peril

"Social insurance is always a result of low wages. Adequate wages would immediately shift the responsibility of meeting such emergencies from society to individuals."—(from Simons and Sinai, in *The Way of Health Insurance*, Chicago University Press.)

A.M.A. Circularizes Abstract of Sickness Insurance Bill

The American Medical Association has sent an abstract of a bill for sickness insurance prepared by the American Association for Social Security, or its secretary Abraham Epstein, to the constituent parts of the American Medical Association. The January issue of the *American Medical Association Bulletin* contains a revised draft. Get it, read it—and ponder!

Society Insurance Information Available

Some of our County Societies are interested in knowing more about Malpractice Defense Insurance. They are interested from various angles. Some would like to see open bids for the group insurance of the State Society. The following are factual statements. The arrangements with the Aetna Life Insurance Company can be terminated at any anniversary date. The State Society has an insurance representative who could turn to other reputable and reliable companies who might take over the group policy of our membership. Before taking up with any new insurer, it must be established that the latter could and would compare favorably with the present carrier in solvency, action, and continuity.

The group insurance plan has been operated for thirteen years and a vast amount of detailed information is at hand. Costs can be computed. They consist mainly of cost in insurance rates, operating cost or expense ratio, and the loss ratio. The latter would be the same for any company writing the Society's business, and the former is found to be lower than that charged "to any kind of insurance by any stock company in the State."

County Societies which are really interested in this question could dispel much misinformation and misunderstanding, if they will assist their members to obtain definite information. Mr. Wanvig, our insurance representative, has a quantity of lantern slides and is a qualified expert on the topic. Why not let him address the members? Likewise why should not the members ask him questions to clarify the situation? Why not?

Exhibits Are Education

Exhibits at the annual meeting are always interesting. If the work of the Committee on Scientific Work, and the committee on its exhibit bear fruit, the scientific exhibit will be better than ever. This is but another form of graduate education for the physician.

Milbank Is Learning

Mr. Milbank, head of the Foundation of that name, held forth to the secretaries of the County societies of the Medical Society of Indiana recently. He said nothing new. He still thinks compulsory insurance is a good thing, but he now concedes that the doctor is the essential factor in the success of any health scheme! There is something gained anyway! He and his employees are not in total accord as regards methods of procedure. Mr. Milbank's education is proceeding, however. He will sooner or later learn that organized medicine is the only group which

can speak authoritatively for the profession and to it he should turn for advice and counsel in working out schemes for the improvement of medical care for the whole people. That is, if that is necessary!

Holds Cost of Hospitalization Is Excessive

Although fewer than 10 per cent of the population are cared for in hospitals in any one year, hospitalized illnesses are so expensive that they consume 50 per cent of the total annual expenditure for all medical care. William Alan Richardson, writing in the January issue of *Medical Economics*, thus explains the growing interest in group provision for hospitalization. "In spite of much loose talk about the high cost of doctoring in the peak year of 1929," says he, "only 29.8 cents out of each dollar spent for individual or public health in the United States went to the private practitioner."

More About Health Insurance

A German labor economist "offers new plan to avoid pitfalls of old one" (the subtitle of his pamphlet). Gustav Hartz asks: "Will America copy Germany's mistakes?" This is a publication of the Pennsylvania Self-Insurers' Association. This booklet should be very carefully studied by the proponents of health insurance. The rest of us suspected long ago what here is set forth! It makes good reading. Get the book. It is worth perusal.

Dr. Frederic E. Elliot, chairman of the Committee on Economics, says: "The American people will be talked into health insurance if every physician does not do his part. He must first become informed, then talk to his own people." Hartz's little booklet will help inform you and give you something to talk about.

Perhaps a United Front

The metropolitan area whose District Branches comprise both the first and second have appointed their conference and study group in accordance with the Council's recommendation. Perhaps a united front will emerge.

Sick Benefits in Germany

How the juggernaut grows is shown by the developments in Germany. In 1913 the German system provided benefits for 134,000,000 days of sickness. In 1928 this figure reached 290,000,000. In 1914 the gross income of various sick funds was 670,000,000 marks (1 mark = about 25 cents). In 1928 this figure had reached 2,100,000,000 marks.

County Societies

Albany County

Mrs. H. P. Mencken, of the Woman's Auxiliary to the Medical Society of the County of Queens, the first one organized in New York State, recently helped organize an Auxiliary to the Albany County Medical Society. She was accompanied by Mrs. Thomas D'Angelo, president of the Queens Auxiliary.

A luncheon was given for them at the De-Witt Clinton Hotel in Albany and was attended by the wives of the officers of the Albany Medical Society.

The organization meeting was held in the Auditorium of the Harmanus Bleecker Library and was attended by fifty doctors' wives. The speakers were: Dr. Arthur Bedell, president of the New York State Medical Society; Dr. Walter A. Reynolds, president of the Albany County Medical Society; and Dr. Joseph Lawrence, secretary to the New York State Medical Society.

Mrs. Mencken addressed the women on the Objects and Reasons for an Auxiliary. Mrs. D'Angelo related the history of the Queens Auxiliary and some of its achievements.

The Albany County Auxiliary was officially organized and officers were elected, as follows: Mrs. Lawrence of Albany, president; Mrs. William P. Howard, vice-president; Mrs. Frank J. Williams, secretary; and Mrs. William J. Fitzgerald, treasurer.

Bronx County

Dr. William Ainslie Goodall, prominent Bronx physician, died in January at the Wickersham Hospital, after a brief illness. He was 72 years old. His widow, Elizabeth Anderson Goodall; a sister, Janet Carruthers, of Windsor, Canada; and a brother, Auls, of Galt, Canada, survive.

He had been active in local medical work for 50 years. He was the first director of the Morrisania City Hospital, on whose staff he remained until his death as a consulting physician.

On May 6, 1933, more than 400 friends and professional associates honored him on his 50th anniversary as physician with a testimonial dinner in the Hotel Astor. The dinner was sponsored by the medical board and staff of the Morrisania Hospital. Speakers included former Hospital Commissioner J. G. William Greeff, Dr. Charles Gordon Heyd, Dr. Nathan D. Van Etten, and former Justice Tierney.

Dutchess—Putnam Counties

At the annual meeting of the Dutchess-Putnam Medical Society held at the Hudson River State Hospital, Dr. John R. Rose, superintendent of the Wingdale Hospital was elected president to succeed Dr. W. W. Thompson, of Poughkeepsie.

Two new members, Dr. Edward W. Briggs of the Harlem Valley State Hospital and Dr. Viola G. Hudhart of the Hudson River State Hospital, were elected to membership.

Other officers chosen were Dr. C. O. Davison, vice-president; Dr. Howard P. Carpenter, secretary-treasurer; Dr. John F. Rogers, associate secretary; Dr. C. Knight Deyo, delegate to the State Society; Dr. A. L. Peckham, Dr. James Toomey, and Dr. G. J. Jennings, censors; George V. L. Spratt, counsel—all of Poughkeepsie.

A paper on "Mental Hygiene and the General Practitioner," with a demonstration of cases, was read by Dr. Solon C. Wolf of the Hudson River State Hospital staff.

Erie County

The Erie County Medical Society, on January 21, following the inaugural address of its new president, Dr. Herbert H. Bauckus, who stressed the importance of providing every sick person with the individual service rendered by the private physician, unanimously approved a resolution to have the city adopt a plan similar to that used in the counties of the State under which needy persons requiring medical care would be referred to private physicians who shall be compensated by the department of social welfare at the rate of \$1 per office call, \$2 per home call, and \$25 per birth case.

This proposal is to be pushed by members of the society among the various civic organizations of the city in an effort to have the City Council adopt it.

Genesee County

Dr. Joseph P. Garen of Olean gave an address on Economic Problems at a meeting of the Genesee County Medical Society on January 22 in Batavia at the Hotel Richmond. He is a member of the Committee on Economics of the State Society.

Dr. Charles D. Graney of Le Roy, president, has appointed the following committees for the year: Public Health, Dr. H. M. Spoford of Batavia (chairman), Dr. Ralph

Frazier of Bergen, and Dr M P Messinger of Oakfield, medical economics, Dr Stanley R Hare (chairman), Dr Loren B Manchester and Dr Peter J DiNatale, all of Batavia, legislative Dr DiNatale (chairman), Dr Charles M Groney and Dr Robert G Wilson, all of Batavia, program, Dr DiNatale (chairman), Dr Hare, and Dr Charles L Davis of Batavia, membership Dr Ward B Manchester (chairman), Dr Edward N Morgan and Dr Irwin A Cole all of Batavia, physiotherapy, Dr Thomas M Steele, of Le Roy (chairman), Dr Frazier, and Dr R L Warn of Oakfield

Kings County

Dr J Sturdivant Read president of the Medical Society of the County of Kings has issued a statement in behalf of the Brooklyn Visiting Nurse Association in which he emphasizes the obligation that rests upon borough citizens to support the Association's work.

The physicians of Brooklyn both as individual practitioners and as members of the County Medical Society, have reason to know and appreciate the work of the Brooklyn visiting nurses [said Dr Read]. The Medical Society of the County of Kings for the last ten years has been in effect the medical advisory board of the Brooklyn Visiting Nurse Association.

The Association has a record of 46 years service in the borough. During this period the staff has grown from one to 141 every one of whom is a registered graduate nurse equipped to give skilled bedside care in the home. The members of the staff of the Brooklyn Visiting Nurse Association are fulfilling their mission in the individual care they give to the sick in their co-operation with the physicians of Brooklyn and in the general cause of public health. Such a service deserves the wholehearted support of the public.

Monroe County

A rich flow of humor was the chief feature, according to all reports of the testimonial dinner tendered on January 15, by the Rochester Academy of Medicine to Dr George Hoyt Whipple, the Nobel Prize winner.

Dr Milton C Winternutz, retiring dean of the Yale School of Medicine, was selected to deliver the principal address. It resolved itself into series of facetious reminiscences gained through almost a lifetime of association with the guest of honor. Delivered with the humor of a professional after-dinner speaker, they kept the audience in constant laughter.

More than a score of internationally famous men arose to pay their personal respects to the quiet Rochester scientist, but nothing remotely approaching a formal address was heard.

With one or two exceptions, nobody spoke more than five minutes, and hardly a technical or scientific word was heard throughout. Humor featured practically all the talks, though with an undercurrent of earnestness.

When Dr Whipple was called upon to reply, he said "I shall never be able to live up to the pinnacle of excellence attributed to me here, and I don't suppose I shall ever be able to live down this occasion. I expect when we leave here tonight stretcher-bearers will carry out all the mangled, maimed, and bleeding adjectives, treat and restore them and finally put them back into circulation on the golf course outside."

The Medical Milk Commission reports that its chief accomplishment for the past year is the elimination of the distribution of all raw milk in the City of Rochester, except certified. This was accomplished after years of effort and the ordinance was passed by the Common Council last summer although an attempt was made to stop it by the use of an injunction. In all probability it will be a permanent situation in Rochester.

It is the desire of the Medical Milk Commission that all physicians become acquainted with the fact that should they wish to prescribe raw milk, there is available an excellent certified supply which is as safe as it is possible to render raw milk. The price is only 4¢ above the charge for the general milk supply.

The Membership Committee of the County Society says that its real task has not been with the young men. They appreciate the value of affiliation with the County and State Societies with its insurance protection and other activities. But the older men who have allowed their membership to lapse not because of any criticism or dissatisfaction but apparently, entirely because of financial reasons present a problem very difficult of solution.

A member to be stricken from the rolls must be in arrears or owe the Society \$32. The Committee suggests that if some arrangement could be brought about whereby that member could be reinstated if he could pay his indebtedness for the current year or make up the amount in installments it might have greater success in bringing back those who have fallen away.

New York County

Most of the abuses connected with the medical service in workmen's compensation "have grown out of suppression of the free choice of physicians and investment of the insurance carriers and employers with control over treatment," said Dr Franklin Welker in his inaugural address as President of the Medical Society of the County of New

York. "There should be," he holds, "a complete separation of financial relief from medical service, with the medical profession in full control of the latter."

The propaganda for health insurance, he holds, emanates "from the small minority that controls most of the nation's wealth," who wish "to prevent any radical changes in the order which favors them so strongly." He riddles the claims for health insurance by pointing out that "over 47 per cent of the population has no illness in a normal year and 90 per cent of those who fall sick suffer from minor ailments for which they are able to provide with no difficulty. Hence, to safeguard 10 per cent of the population, 90 per cent are to be required to pay a sum that, in many cases, would entail a definite drop in living standards. If the system is to apply to the entire population, as one of the so-called reformers suggests, you will have the ironic spectacle of the 80 per cent who are earning under \$2,000 a year contributing to the sickness expense of people with five or ten times their income."

The best way to provide medical care for those unable to pay, in his view, is some arrangement like the Geib-Vaughn plan, "which has met with such success in Detroit, or the comparable method adopted here in the past few years by Federal and local emergency relief administration. Just as the individual on relief has his rent paid and is given food tickets, he receives an authorization for medical care when ill. He may be treated by any licensed practitioner enrolled for this work and the government pays the bill in accordance with a fixed fee schedule."

Dr. Walter T. Dannreuther, in his address as retiring president, defended the Comitia Minora of the County Society against charges that it is "a self-perpetuating body." "A detailed analysis of this personnel over a period of years refutes this allegation," he asserted.

The New York Physicians' Art Club will hold its 8th Annual Exhibition for two weeks, beginning March 30, at the New York Academy of Medicine, 5th Avenue and 103rd Street. The officers of the Club are Howard Lilienthal, president; W. Morgan Hartshorn, treasurer; Louis C. Schroeder, 50 East 72nd Street, secretary, to whom all communications should be addressed. The members, who pay no dues, but only a fee with their exhibits to pay expenses, are mostly New Yorkers, but any physician is welcome to send in original art works to the showing. Former exhibitions have opened with a dinner of members and guests, and informal talks by artists, critics, and amateurs. These exhibits included oils, water colors, lithographs,

sculpture, photographs, pastels, wood carving, book plates, ship-models, etchings, jewelry, wood-inlays, and book bindings.

Dr. Robert James Carlisle, for 46 years a member of the faculty of New York University and Bellevue Hospital Medical College, died of coronary thrombosis in the hospital, where he was a member of the staff. He is survived by his wife, Mrs. Mary Alice Dominick Carlisle.

Dr. Carlisle, a teacher and consultant in internal medicine, was born in New York City on December 5, 1859. His father, Hugh Carlisle, was a New York teacher, in whose memory Carlisle Public School was dedicated. On his maternal side Dr. Carlisle came from old American stock. The founder of the American Line, Thomas White, came to Massachusetts from England in 1636, 16 years after the *Mayflower* voyage. Many of Thomas White's descendants were physicians and ministers and one, Dr. Oliven White, became a prominent practitioner in New York and was one of the founders as well as vice-president of the New York Academy of Medicine.

Oneida County

The annual meeting of the Medical Society of the County of Oneida was held in Utica on Tuesday, January 8, following luncheon at the Hotel Utica. Dr. E. E. Powers presided. The election of officers resulted in the following being chosen: President, M. D. Graham; vice-president, Dan Mellen; secretary, William Hale, Jr.; treasurer, H. D. MacFarland; librarian, T. Wood Clarke; delegates, G. M. Fisher and E. M. Griffiths; censors, W. B. Roemer, E. E. Powers, F. J. Rossi, G. A. Holden and H. M. Young; alternates, B. P. Allen and C. D. Quinn.

The secretary reported for the year, enumerating the new members elected, the loss of members by death and transfer to other counties, and the speakers of the year, three-fourths of whom were our own members. The treasurer reported a balance on hand with very few delinquents. Dr. T. H. Farrell, chairman of the Public Relations Committee, gave a report of the work done by the Committee during the year, calling attention especially to the survey of maternal deaths and attention called to this matter on the occasion of Mother's Day, the survey of Health Agencies in the city of Utica, and the proposal to use private hospitals for the overflow of the Oneida County Hospital. Later a motion was put through recommending to the Board of Supervisors a minimum fee at which the physician would care for any overflow of patients from the Oneida County Hospital into private hospitals.

For the Committee on Medical Economics, in the absence of Dr. F. M. Miller, chairman, his report was read by Dr. John Gromann. It outlined the activities of the local Committee in connection with the Committee on Medical Economics of the State Society, of which Dr. Miller is a member.

For the Board of Censors, Dr. Roemer read the application for membership of Dr. Harry B. Luke of Marcy State Hospital, Dr. Paul Cahn, and Dr. Herman J. Segaul, who were elected.

The scientific program consisted of the retiring president's address in which Dr. Powers reviewed medical practice in its ethics and technic, and pointed out pitfalls that must be guarded against in the near future.

A motion picture film was shown by Mr. R. C. Mill, representative of the Mead-Johnson Company, entitled "The Fertilization of the Human Ovum."

Queens County

The Queens County Auxiliary is making plans for its second anniversary birthday party in March. It was the first auxiliary organized in the State. It is hoped that many other counties will form auxiliaries and finally stimulate the formation of a State Auxiliary. States in which Women's Auxiliaries have been formed have found such an organization of marked benefit to the State Society. They have contributed to the attendance at State Meetings where the women of the local Society have acted as hostesses to the wives and members attending the functions.

The library of the County Society has received a gift of \$200 for the purchase of books. Last year was the best in the history of the society's *Bulletin*. It more than paid its way and only a small amount is still due from advertisers.

The Queensboro Council of Social Agencies is offering citizens of Queens an opportunity to discover and discuss the local slant on health and national problems as they affect Queens in its series of six forums—on January 29; February 5, 19 and 26; March 5 and 12, at Public School No. 20, Sanford Avenue and Union Street, Flushing.

These forums, under the general title of "What Queens Needs" will take up such current and vital topics as "What Queens Needs in a Preventive and Remedial Health Program," "Character Building and Crime Prevention," "Low Cost Housing," "Wide Recreational Programs for Young and Old," "Effective Educational Opportunities for All Children," and "A Program of Adult Education."

A panel of prominent citizens has been

selected by the Queensboro Council of Social Agencies to meet with each speaker before each forum. These meetings will develop the most vital issues and important facts on them, to be brought out at the forums. A different panel has been arranged to precede each forum, thus insuring varied and representative opinions on every topic.

Schenectady County

Dr. Roger Anderson of Seattle, Washington, whose discoveries have changed several medical theories, addressed a large meeting of the Schenectady County Medical Society at Ellis Hospital on January 18.

He explained methods of treating fractures of the lower extremities which he announced two years ago. His lecture was supplemented with moving pictures and lantern slides and was followed by an intensive discussion.

There were present representative groups of physicians and surgeons from Albany, Troy, Amsterdam, Saratoga Springs, Ballston Spa, Gloversville, and several other communities.

Dr. Anderson's treatment entails the placing of a cast on both legs when there is a fracture of a hip or leg. The well leg serves as a leverage for the injured leg and serves to keep both the same length and hastens recovery.

Among the many advantages cited for the new system are: Patients may sit up within a day or two after the fracture has been reduced, there is less shock, they can leave the hospital sooner, and they are more easily handled by their nurses.

Westchester County

The Westchester Comitia Minora has officially endorsed the movement of the County Pharmaceutical Association to issue blank prescription forms to physicians. It feels that every step must be taken to disabuse the public of the notion that certain individual doctors derive commissions from certain pharmacists for prescription business supposedly referred to them.

Wyoming County

The Wyoming County Medical Society held its quarterly meeting at the Castile Sanitarium, Tuesday, January 8. Dinner was served at noon to the doctors and their wives, after which all attended the scientific program in the gymnasium.

Dr. J. W. Gallagher of Perry, president of the Society, opened the meeting and after the routine business discussion, introduced the invited speaker of the day, Dr. Margaret Warwick of the Millard Fillmore Hospital, Buffalo. Her subject was "Benign and Malignant Tumors."

York. "There should be," he holds, "a complete separation of financial relief from medical service, with the medical profession in full control of the latter."

The propaganda for health insurance, he holds, emanates "from the small minority that controls most of the nation's wealth," who wish "to prevent any radical changes in the order which favors them so strongly." He riddles the claims for health insurance by pointing out that "over 47 per cent of the population has no illness in a normal year and 90 per cent of those who fall sick suffer from minor ailments for which they are able to provide with no difficulty. Hence, to safeguard 10 per cent of the population, 90 per cent are to be required to pay a sum that, in many cases, would entail a definite drop in living standards. If the system is to apply to the entire population, as one of the so-called reformers suggests, you will have the ironic spectacle of the 80 per cent who are earning under \$2,000 a year contributing to the sickness expense of people with five or ten times their income."

The best way to provide medical care for those unable to pay, in his view, is some arrangement like the Geib-Vaughn plan, "which has met with such success in Detroit, or the comparable method adopted here in the past few years by Federal and local emergency relief administration. Just as the individual on relief has his rent paid and is given food tickets, he receives an authorization for medical care when ill. He may be treated by any licensed practitioner enrolled for this work and the government pays the bill in accordance with a fixed fee schedule."

Dr. Walter T. Dannreuther, in his address as retiring president, defended the Comitia Minora of the County Society against charges that it is "a self-perpetuating body." "A detailed analysis of this personnel over a period of years refutes this allegation," he asserted.

The New York Physicians' Art Club will hold its 8th Annual Exhibition for two weeks, beginning March 30, at the New York Academy of Medicine, 5th Avenue and 103rd Street. The officers of the Club are Howard Lilienthal, president; W. Morgan Hartshorn, treasurer; Louis C. Schroeder, 50 East 72nd Street, secretary, to whom all communications should be addressed. Oneida County

The annual meeting of the Medical Society of the County of Oneida was held in Utica on Tuesday, January 8, following luncheon at the Hotel Utica. Dr. E. E. Powers presided. The election of officers resulted in the following being chosen: President, M. D. Graham; vice-president, Dan Mellen; secretary, William Hale, Jr.; treasurer, H. D. MacFarland; librarian, T. Wood Clarke; delegates, G. M. Fisher and E. M. Griffiths; censors, W. B. Roemer, E. E. Powers, F. J. Rossi, G. A. Holden and H. M. Young; alternates, B. P. Allen and C. D. Quinn.

The secretary reported for the year, enumerating the new members elected, the loss of members by death and transfer to other counties, and the speakers of the year, three-fourths of whom were our own members. The treasurer reported a balance on hand with very few delinquents. Dr. T. H. Farrell, chairman of the Public Relations Committee, gave a report of the work done by the Committee during the year, calling attention especially to the survey of maternal deaths and attention called to this matter on the occasion of Mother's Day, the survey of Health Agencies in the city of Utica, and the proposal to use private hospitals for the overflow of the Oneida County Hospital. Later a motion was put through recommending to the Board of Supervisors a minimum fee at which the physician would care for any overflow of patients from the Oneida County Hospital into private hospitals.

plaintiff's testimony that the operation was completed with the same instrument claimed to have been broken. It was brought out that if broken as the plaintiff contended, the instrument would have been useless, but the plaintiff had proceeded on the theory that there had been no substitution of instruments, although both tonsils were completely removed.

The plaintiff's case was practically devoid of any expert testimony for the purpose of connecting the injuries claimed with the alleged negligence. One man was called as a witness who had taught physiology, and had been a sanitary officer of the United States in the World War, and he undertook in part to explain the manner in which the piece of metal had reached the region of the anus, and the sort of injuries it might cause. The competent testimony, it seems, was all to the effect that the fragment could not have reached the point in the perineal tissue from which it was removed without cutting its way through the lower bowel into the perineal tissue. In the process of so changing its position, it was brought out, a foreign body would necessarily infect the perineum and cause a painful abscess, and there was no evidence that such a condition had existed.

Particularly important in the defense's expert testimony was the evidence given by several physicians that the progress of a foreign substance through the body would have caused no pain such as the plaintiff had described. One of the doctors so testifying said in part the following:

Q. What particular foreign bodies have you known to enter, and pass through the intestinal tract? A. You can mention most anything in existence.

Q. Well, hard or metallic substances or sharp substances particularly? A. The more common ones are safety pins and tacks.

Q. Closed safety pins? A. Well, both closed and open.

Q. What about foreign bodies, doctor, in the stomach; do you mean to testify that they don't agitate or irritate the stomach or cause any damage there? A. I don't believe I so stated.

Q. What would be the effect if you had a foreign body or object such as "Exhibit J" lodged in the body with these sharp corners on, lodged in the stomach? A. "Exhibit J" was the piece of metal I was shown?

Q. Yes. A. I don't think there would be any effect at all.

Q. You think that wouldn't cause any irritation in the stomach at all? A. I think

it very unlikely it would cause any irritation.

Q. Why do you say that, doctor? A. Because so many things of that kind are swallowed and pass through the stomach without causing any trouble.

Q. You say that you had experience once with the neck of a vanilla bottle passing through a person? A. Yes, sir.

Q. Was that your own case, doctor? A. Yes, sir.

In addition thereto the defendant's experts gave testimony that the patient's complaints of ill health and pains over the period of years were chiefly due to nervousness in connection with her menopause, which she went through at the time.

At the conclusion of all the testimony the defendant applied for a directed verdict, and the court granted the motion on the grounds that the cause of action was barred by the statute of limitations, and further that there was not sufficient evidence to justify submission of the case to the jury. From the judgment entered on the verdict, the plaintiff took an appeal.

On the appeal to the Supreme Court of the State the judgment of the court below was affirmed by a divided court. The Supreme Court held that the statute of limitations was a complete defense, but they went further and said that disregarding this technical defense the plaintiff had not on the trial adduced sufficient proof to warrant the submission of the case to the jury.

Broken Screw in Leg

A middle-aged man was struck by a hit-and-run driver and taken to a hospital. He was found to be suffering from a fracture of the mid-third of the tibia with posterior and internal displacement of the upper fragment and overriding amounting to over an inch. He was found also to be suffering from tertiary syphilis. The reduction of the fracture was delayed by reason of ulcers and blisters on his leg at the site of the fracture of the tibia. After he had been in the said hospital as a patient for a week he was transferred to a second institution for the purpose of receiving treatment for both the fracture and syphilis. At that hospital he came under the care of the defendant doctor, a general surgeon. The doctor when he first examined the patient found that the fracture had been unreduced for too long a time for him to attempt a manual reduction.

Preliminary treatment was given to the patient to build him up physically for an

operation and an operation at the end of a week was performed for the purpose of inserting a Lane plate. When the doctor was inserting the screws, through some defect in one of the screws it broke and the tip of the screw remained imbedded in the tibia. The patient was under a spinal anesthesia and was told of the occurrence and told that no attempt would be made at the time to remove it, for in order to get it out it would be necessary to gouge out a large piece of bone which would be dangerous in view of the patient's condition of syphilis. Patient remained in the hospital for about two months and had an uneventful recovery. Some time thereafter the plate was removed from the patient's leg and again since the fragment of the screw was doing no harm it was left in the leg.

The screw remained in the patient's leg for somewhat over five years when the patient consulted another doctor with respect to a condition of osteomyelitis. At that time x-rays showed presence of the

screw and the doctor then in charge of his case, decided to remove the screw, at the same time he treated the condition of osteomyelitis, although he did not find any apparent connection between the presence of the screw and the disease.

Some time later the patient instituted a suit against the first surgeon based upon his failure to remove the fragment of screw from the leg at the time it broke off. The action was not started until a considerable period of time had elapsed and, therefore, the two-year statute of limitations applicable to malpractice actions was a bar to the chief complaint of the plaintiff, that is, the complaint of improper treatment. However the plaintiff proceeded on a cause of action based upon an alleged breach of contract. When the case was about to be reached for trial the plaintiff obviously feeling that it was impossible for him to prove the cause of action, stated in his complaint, voluntarily discontinued the action against the doctor.

Books

REVIEWED

Recent Advances in Ophthalmology.—By Sir Stewart Duke-Elder, M.D. Third Edition. Octavo of 434 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, Inc., 1934. Cloth, \$4.00.

To anyone who has followed the very interesting growth of *Recent Advances in Ophthalmology* as it has appeared in successive editions, the appearance of the new volume is an added pleasure. That the work presents in an orderly manner the progress of certain fields of ophthalmology is obvious, but one finds certain questions quite definitely answered—questions which have been becoming prominent for the past two or three years. E.g.: What is the accepted status of the etiology of trachoma at a time when Noguchi's classical studies were reviewed by numerous workers? Another question: In view of the demonstrated absence of dilator fibers in the retinal vessels, what is the mechanism by which their caliber is increased so obviously in various diseases? What is the status of radiation treatment of intraocular tumors? What is the difference between epidemic herpes zoster and simple herpes of the cornea? What are the present views on the pathogenesis of such conditions as cataract, sympathetic ophthalmia and glaucoma? These questions and innumerable others are discussed in a clear and delightful manner in this the third edition of *Recent Advances in Ophthalmology*.

The reviewer can only hope that there will be no interruption in presentation of successive editions, for each is a delightful stimulus and convenient means of keeping up with the times.

JOHN N. EVANS

Diseases Peculiar to Civilized Man.—Clinical Management and Surgical Treatment. By George Crile, M.D. Octavo of 427 pages, illustrated. New York, The Macmillan Company, 1934. Cloth, \$5.00.

This is a unique book, the theme of which is that neurocirculatory asthenia, hyperthyroidism, peptic ulcer, diabetes mellitus, and epilepsy are related diseases. These diseases are presumably due to increased activity of the brain-thyroid-adrenal-sympathetic system, "the kinetic system." The control of this increased activity

or hyperkineticism may be brought about by the removal of the thyroid, the excision of certain sympathetic ganglia, or denervation of the adrenal glands. The treatment may involve only one point of attack or in some instances more than one, before the desired result may be obtained.

The first half of this book is devoted to a consideration of the background of these diseases, their symptomatic manifestations, the diagnostic methods, and the rationale of the surgical therapy that has been applied. That part, dealing with the surgical anatomy, the operative technic, the postoperative complications and the end results following adrenal denervation, should be of special interest.

The second half of the book consists of case histories with interesting comments listed as progress notes. In addition to the previously mentioned disorders, Dr. Crile has given a short account of his experience with the psychoneurosis and arterial hypertension.

The book should be well received and certainly clarifies many uncertain rumors regarding adrenal denervation that have supposedly emanated from Dr. Crile's clinic.

JEFFERSON BROWDER

Modern Treatment in General Practice.—Edited by Cecil P. G. Wakeley, D.Sc., F.R.C.S. Octavo of 426 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$4.00.

This is a reprint of a useful series of articles which appeared in the *Medical Press and Circular* of London. There are 56 practical discussions on the treatment of various diseases, among them "Diabetic Coma," "Acute Circulatory Failure," "Burns and Scalds," "Obesity," "Syphilis," and many others. In the article on the "Etiology and Treatment of Disseminated Sclerosis" the possibility of infection as cause is considered and a relationship is suggested to post-vaccinal encephalitis, post-measles encephalitis, and acute disseminated encephalo-myelitis.

The subject matter is generally easy to read and presents much of interest.

WILL AMERICA COPY GERMANY'S MISTAKES?

EDITOR'S NOTE: The following excerpt is from a release issued to the press by the Bureau of Public Relations of the Medical Society of the State of New York.

ALBANY, N. Y., Feb. 24, 1935.—“The acid test of experience condemns compulsory health insurance schemes wherever they have been tried,” stated Dr. Arthur J. Bedell, president of the Medical Society of the State of New York here today, in opposing the bill now pending in the State Legislature.

“The medical profession disapproves of the proposed law because this method of handling medical care is damaging to the patient and disastrous to the doctor.

“This protest does not mean opposition to the policies of the administration in its recovery efforts or in any other phases of the ‘New Deal.’ However, physicians as a class are better qualified to speak than any other group, as to the effects of a compulsory health insurance law on the community, and the Medical Society of the State of New York, representative of the physicians of the state,

GUSTAV HARTZ

Labor Economist of Berlin, author of this pamphlet and of several books on Germany's social politics. He says that the social insurances of his country are largely responsible for her present plight, and he suggests a new plan for looking after unfortunates without making their misfortunes permanent.

rejects the project because it will not work, and because what it will bring to the community is quite the opposite of the expectations of its well-wishing proponents.”

Dr. Bedell pointed to the utter failure of compulsory health insurance in Germany, where it has been tried for half a century. He said that Gustav Hartz, labor economist of Berlin, and author of several books on Germany's social politics, has analyzed the fallacies of the scheme and exposed to the world the harm, rather than good, that compulsory health insurance has actually produced. Dr. Bedell stated that Mr.

Hartz' valuable report which is entitled, “Will America Copy Germany's Mistakes?” is to be reproduced in full in the March first issue of THE NEW YORK STATE JOURNAL OF MEDICINE as translated from the German by the Pennsylvania Self-Insurers' Association of Philadelphia.

German Labor Economist Offers New Plan to Avoid Pitfalls of Old One

FOREWORD

"The proof of the pudding is in the eating thereof."

If compulsory social insurances are desirable, as the powers that be in America today seem to think they are; if they are to be amplified and pyramided in the hope of improving the condition of the people as a whole by promoting peace, contentment and security, there should be unmistakable and indubitable evidences of these highly-desirable ends in the older countries of Europe where social insurances originated and where they have been in actual operation over a long period of years.

This pamphlet is a brief resume of two books written in Germany by Gustav Hartz, of Berlin—"Irrwege der deutschen Sozialpolitik," published in 1928, and "Bankbuch Statt Almosen," not yet in print. The titles translated mean, "Errors of Germany's Social Politics," and Bank-book Instead of Alms."

Feeling that our legislators should be fully informed before committing themselves to irrevocable mistakes, the Pennsylvania Self-Insurers' Association persuaded Mr. Hartz to attempt a digest of his studies, covering half a century of practice in Germany.

First, a word about Mr. Hartz himself. He was a workman and his father before him was a workman. Orphaned at the age of 11 years, he was taken in by a peasant neighbor, who brought him up at the expense of the national welfare funds. His youth was one of grinding poverty and hard work. At the age of 18 years, he joined the clerks' trade union and rapidly rose to leadership in the organization.

Until trade unions were abolished under Hitler—an inevitable result of Government management, which some of our own Labor leaders do not seem to realize—he continued to be one of their outstanding spokesmen.

Mr. Hartz served through the war and received the Iron Cross for gallantry in action. He became a member of the Reichstag, and is at the present time connected

with the largest publishing firm in Berlin.

His books are written from the workmen's point of view, not the employers', and they are based upon a study of facts and procedure which has given him a place as one of the foremost economists of his country.

He is not one of those who would tear down something and leave nothing in its place, but he has a plan of his own which he considers infinitely superior to social insurance, namely, compulsory savings. He proposes that every worker be compelled by law to save a certain percentage of his earnings, deposit them at interest in his own name in a bank under Government protection, and out of them, take care of his own rainy days; create his own security.

The plan is quite ingenious and was receiving the serious consideration of the Nationalist party leaders, before they and all other parties were overthrown by Hitler and his Nazis.

Mr. Hitler himself seems to be well aware of, and to some extent in sympathy with, Mr. Hartz's ideas, for he is ruthlessly revolutionizing management and policies of the bankrupt funds, and has even abolished unemployment insurance for domestic servants, because he discovered that it, in turn, was abolishing domestic employment.

Of course, the same tendencies, if not in the same degree, must ultimately be felt in all other lines of human endeavor, for whatever increases business hazard, dampens business enterprise.

We submit this pamphlet for the edification of those who are still able to subscribe to the fine old motto on the walls of our House of Representatives at Harrisburg:

"Ye shall know the truth, and the truth shall make you free."

WILL AMERICA COPY GERMANY'S MISTAKES?

Results of a Half a Century's Practice of Social Insurance in the Land of its Inception

GUSTAV HARTZ

Written and translated for the Pennsylvania Self-Insurers Association, Finance Building, Philadelphia

Reprinted by Permission

Reasons for the Introduction of Social Insurances

Almost exactly 50 years ago, the first law of modern workmen's insurance (social insurance) of the world came into force. It was the law referring to sick insurance for industrial workmen in Germany. Starting in Germany the idea of social insurance spread but slowly, but ultimately found its way into many States. It became the basis and corner stone of modern workmen's social politics.

When, under the great statesman Bismarck's chancellorship, social insurance was first introduced, he was, and not without reason, warned against taking this "jump in the dark," for nowhere did any experience in the matter exist.

Now, the introduction of social insurance no longer means jumping in the dark; we look back upon an experience of 50 years, that points out the way to real social politics—and at the same time shows how they should not be made.

It is not advisable to give ear to the biased experiences of advocates of social insurance who, in many cases, draw profits therefrom, for there is no institution in all the world that is so much extolled and the praise of which is so little justified as social insurance. The cause for this praise is to be sought in its sound ideas and good purposes which none but those devoid of all moral sense can dispute. Who could be hardhearted enough to stand by and watch a fellow creature starve or drown, had he the power to save his life?

Abou-ben Adhem Antedated Marx

Help in need is a matter of course based upon Christian charity and morals.

No one can deny that this is the soil the idea of social insurance sprang from; this, coupled with the consideration of clever, far-seeing statesmen who recognized in increasing poverty and dissatisfaction a

danger for the State which they wanted to evade. The motive for the introduction of German social insurance was a very simple one which has, in its fundamental idea, become typical for all States, however much the outer causes and the strength of the single reasons may differ.

Men Gathered in Industrial Centers

Owing to the rapid development of industry the number of industrial workers greatly increased and went on increasing. They crowded more and more into the big towns and industrial centers. The conditions of life were none too good. Wages were low and the workmen had no resources to fall back upon. The industrial proletariat, whose only capital was their capacity to work, had sprung into being. Should they lose their working power entirely, or even temporarily, their families would be faced by dire want. They would be destitute, have to rely upon the charity of their fellowmen, or would be forced to accept the help of the community. And the life of those who were lucky enough to have work was clouded also by doubts concerning the future.

Among these discontented masses the firebrand of the doctrines of Marx, attacking the State and the existing social order, was flung. Though the socialist laws forbade Marxist organizations and open propaganda, the doctrines crept in through a thousand channels finding a fertile soil among the proletariat, and it took on dimensions that threatened to endanger the State.

These State-political reasons were primarily decisive in the establishment of social insurance.

It's All "Unemployment" Insurance

The State wished to relieve the workmen of the anxiety for future disability, when they might find themselves without earnings. It also wanted to put an end to

their grumbling, to crush revolutionary aspirations; in short to turn the workmen into contented citizens.

Added to this was a high sense of moral and religious duty, a feeling of charity, and the State leaders' sense of responsibility for the poorer classes.

To consider unemployment insurance an achievement of recent years, to call it the "crown of social insurance" is a mistaken view, for every social insurance is an unemployment insurance, whether the unemployment is due to illness, accident, early incapacity, old age, or to being out of work.

The introduction of social insurance has at all times and everywhere been caused by too dense a population that has got into trouble through loss of wages, and was unable to bridge over the time of waiting from its own private means. Whether that class came into existence through the colossal social transformation in Germany 50 years ago, or now, owing to the devastating economic world crisis brought about by unemployment, is of small importance.

Poverty the Cause of Social Insurance

It must be stated here that neither unemployment, accident, incapacity nor old age created the necessity for the State's establishing social insurance. Ever since the beginning of civilization the lives of all humanity have been accompanied by such hazards—that of the millionaire as well as of the proletarian, of master as well as of man, of the head of the State and the crossing-sweeper, whereas social insurance is but 50 years old. I have never heard of a State introducing a sick and old age insurance for millionaires or an unemployment insurance for manufacturers and other employers, although in all States there are many to be found who not only work without profit but even at a considerable loss. And yet sick and old millionaires have certainly been known to exist. Are these citizens of smaller value to the State leaders than they are passed over by social welfare?

Social Insurance Creates Poverty Instead of Curing It

The reason for this is of an entirely different nature. Those people have their resources, they are provided for by their own private means. Should the State make provision for sick millionaires or be willing to allow employers 50 per cent of their losses at times when they are making no

profits, the statesmen supporting this plan would certainly be considered insane. This representation may seem rather crude but it shows the complaining sick, unemployed, invalid or superannuated workmen the actual cause that led to the establishing of social insurance. The poverty of the masses!

Destitution in consequence of unemployment that befalls the impecunious is not really a social malady but rather a reaction, a fever, produced by a deep-rooted social disease, the masses' lack of means. Social insurance is as it were an injection against the fever, which however does not reach the actual seat of the disease. On the contrary frequent injections are harmful to the constitution and aggravate the disease.

It may easily be proved that social insurance is not only caused by lack of means, but it even makes of it a social principle, aggravates and spreads it, makes it permanent.

In the past century the opinion prevailed—chiefly in Europe—that for capitalist development it was an absolute law of nature that capital should be concentrated in an ever-decreasing number of hands, until the State confiscated all property, placing the administration in the hands of "society"—while on the other hand the number of the penniless constantly increased till all were poor. (This is the direct way to Bolshevism as it exists in present-day Russia, a deplorable end to social efficiency.)

Though the results did not prove this opinion to be correct and the number of capitalists of all countries grew immensely in the last century, the number of the impecunious has in consequence of the increased population, also constantly grown, giving food to the working classes' dream of everlasting poverty as their irretrievable fate.

"Property Means Robbery"

Proletarianism! Poverty! These came to be literally worshipped. Honest workmen were made to believe it their solemn duty to be penniless. The words of the French socialist Proudhon, "property means robbery," became their motto. Hate and envy of capital and capitalists flourished. The dissension of the classes grew into a class war that shook State and economics to their very foundations.

The instinct given man by nature to hoard for eventual times of need, which forms the basis of accumulating money and of acquir-

ing property—upon this all culture and progress are founded—could only be completely killed by a communistic socialistic vision in which people were not obliged to put money by out of a sense of self-preservation because they were shielded from the worst, from direct necessity, by social insurance

Our Workmen Were Not Proletarians

The best counter examples are the United States where, until the great crisis started, communistic-Marxian ideas could not strike root among the working classes, simply for the reason that they were not "safeguarded" by insurance, but the workmen, having to provide for themselves, put money by for a rainy day and were therefore in the Marxist communistic sense not proletarians such as had been carefully bred in Europe

One might have supposed that in Germany, with the most widely developed social insurance system in the world, a country where every workman was provided for in all contingencies of life—where the future mother was cared for, the first milk for the infant provided, where the funeral expenses, or those the deceased left behind were not forgotten by the social insurance, a social upheaval would be least felt. No proofs need be given for the fact that the reverse actually occurred

The Gun Went Off at the Wrong End

The State political results expected of the establishment of social insurance, viz, making the workmen contented and loyal citizens, were not only negative, but they actually led to ends opposed to those anticipated

No doubt these were not the only causes. Social insurance was however in so far responsible as the State by relieving the workmen, to a great extent, from the burden of having to provide for themselves, posed as the great 'benefactor'

This made it the scapegoat upon which all demands, all discontent were thrust. The so-called self administration of social insurance by the circles concerned, did nothing to improve the situation. Discontent and grumbling did not cease, it grew. This arose from the social insurance principle, which is only able to grant a minimum, and the odium of the insufficiency accompanying it, in connection with which the saying was coined 'too little to live on and too much for starving'. From the very beginning the social insurance legislation was scoffed at by the radicals who called it 'Beggars' soup politics' and they

never ceased demanding an increase of the allowances

That these demands, viewed with the eyes of the workman, were socially justified, and that the name given it by the people was not far from the mark, may be gathered from the following figures

Benefits Hopelessly Inadequate

The average old age and incompetence annuity at the present time amounts to

	Per month approximately
For the person insured	*M 28 [\$7 00]
Widows pension	M 18 [\$4 50]
Orphan's allowance	M 10 [\$2 50]

Sick allowance amounts approximately to half of the earnings

The same stands for the unemployment insurance

One can well imagine the feelings of a workman who for years, or for decades, has subscribed high dues but who rarely, in some cases never, made use of the insurances, now that he is ill or has lost his job he has to manage with half the amount of his wages, or in old age gets an insufficient allowance. Must he not grumble at his beggar's dole?

More Peace Promised, More Struggles Resulted

On the other hand the principle of keeping the allowance on an insufficient scale must be persevered in. For should the allowance equal the wages the consequences would prove ruinous to the workman's morale if in case of sickness he drew an equally high amount as that earned by hard labor

These incompatible contrasts are bound to be followed by new struggles. By means of the social insurance "the fatherland was to be supplied with new, lasting guarantees for inner peace," instead of which more and more social struggles ensued, which influenced the formation of political opinions more strongly than anything else

In States governed by parliaments with equal votes for all, the opposition, unbarrased by responsibility, use social political aspirations as the most efficient auxiliary for canvassing among the working classes. Whosoever promises most gets the most votes and with them the greatest

* Exchange on gold standard 4 20 marks to the dollar

political power. Social democracy in Germany, until its collapse, owed a great deal of its success to social insurance.

Social insurance was created in the struggle against social democracy. It became the strongest aid in forming political opinion in their favor. To use their own words, it got to be the "fourth pillar of their power."

Best Promiser Gets the Votes

All political groups happening to be in power have been, again and again, in consideration of impending elections, compelled to make concessions incompatible with reason and without economically sound foundation.

Though the greatest social crisis the world has ever seen may have been caused by many other factors, particularly by the war and the divers new phases brought about by it, that destroyed property accumulated in many generations, and by which a considerable part of social fundamentals were destroyed, the extent of the crisis in many countries did not become so great in spite of, but on account of, the existence of social insurance.

The social crisis has not been alleviated but, to the contrary, has been considerably aggravated by social insurance.

Woe to the State which imagines that crises may be alleviated or stopped by the introduction or the existence of a comprehensive system of social insurance! Sad disappointment awaits it. Every economic crisis swallows up the best organized social insurance and consumes its funds at both ends—at the end of the diminishing premiums and at the end of the increasing benefits.

Can We Hear This Warning?

The reason for this is chiefly that the greatest number of social insurances are not based on actuarial reserves as in the case of life insurance, but on a system of funds sufficient to cover the demand. They do not accumulate in long spaces of time a sufficient capital for future payments, but they live from hand to mouth. This method takes the premiums with one hand from the healthy and from the employed and pays it at once with the other hand to the unemployed and sick. Small reserves by no means improve this condition.

In the unemployment catastrophe the results were as follows: the number of unemployed increased with startling rapidity while that of the workmen still employed and paying premiums was continually diminishing. These premiums no longer

sufficed and had therefore to be raised. They went up from 3 to 6½ per cent of the wages. In the most critical time, when benefits were being reduced, and economic expenses increased, the wages were cut still more. To raise the premiums still further was simply impossible, and thus the allowances had to be repeatedly decreased. This procedure in each case increased the social tension.

Premiums Went Down; Benefits Went Up

The same methods had to be applied to sick insurance and old age pensions, for there the increasing unemployment resulted in a rapid diminution of premiums, while the expenses of the former remained almost the same, and of the latter increased incessantly. The disability insurance was insufficiently covered, due to loss of capital through the inflation and increased allowances. Having been reduced to the apportioning system, it lived from hand to mouth.

Business concerns were no longer able to pay the accident insurance dues. In some trade associations 50 per cent of the rates had to be obtained by levy of distress. The miners' pensions were repeatedly on the point of stopping payment.

In the time of her hardest social crisis, social insurance was Germany's greatest inner trouble.

The saddest inner-political heritage the new German government was forced to accept was the social insurance, the most vital part of which was on the point of collapse.

Not only in times of economic stress does the apportioning system heighten the crisis, but also in times when economics are on the upward grade, for then increasing receipts and decreasing expenses form a great temptation for raising the allowances, besides which it may lead to many unnecessary capital investments.

How the Budgets Jumped

It was in this way that the budget of the sick insurance rose in the years of apparent prosperity to the extent of 200 millions annually, reaching in 1929 the fantastic sum of 2,300,000,000 marks. In 1913 the budget of the sick insurance was still 660,000,000 marks. The same thing was to be found everywhere: in 1913 the budget of the entire social insurance system was

1,300,000,000 marks; in 1930 approximately 6,000,000,000.

And this without the expenses of public welfare that finally bore the greatest part of the burden of unemployment. The entire social budget, namely, social insurance plus welfare, amounted to 2,100,000,000 marks in 1913, but in 1930 this budget reached 10,800,000,000 marks.

But when the economic crisis came the promised and vested payments could not be kept up.

In treating with this subject we should constantly bear in mind that social insurance is a legal contract, based upon premiums paid and guaranteeing definite benefits, whereas voluntary relief is always at liberty to adjust itself to circumstances.

In Germany, nevertheless, the legally reinforced social insurance contracts then had to be changed and partly cancelled, and the "legal rights" only continued to exist on paper.

"Progress" That Proved to Be Fictitious

Yet it was the legal claim which had been played up as the real progress in social security.

In true insurance, the amassing of adequate capital is only possible when an approximate preliminary calculation of the demands can be made, as in the case of life insurance, which is based on mortality tables and similar actuarial statistics.

The risk of unemployment cannot possibly be mathematically calculated. Unemployment is a risk actuarially unascertainable.

Fixed Payments Can't Be Guaranteed

The name unemployment insurance serves to mislead public opinion. It should be called unemployment reserves, where the persons concerned bind themselves to pay a certain contribution, and where they are told: if you are unemployed you may "perhaps" get so and so much, but maybe only so and so much. Fixed amounts can of course be promised, but should the sums be insufficient the premiums must be raised.

To establish an unemployment insurance and to promise an unemployed man certain fixed payments against certain premiums—any mathematician who goes into the problem and declares it sound ought either to be knighted or hanged. I should certainly vote for the latter proceeding, knowing him to be a swindler. Or else an "insurance"

is made where every payment the single individual receives is strictly limited to the amount he has paid in, and then ceases. But then he would be just as well off if he himself saves his premiums.

"Not an Insurance Really"

In Germany the most firmly convinced fanatics on social insurance—such people do still exist and in most cases they fare very well—are even now sure that unemployment insurance "is not an insurance really." In 1927 this "Crown of social politics" was introduced, with fixed premiums and fixed benefits. Three or four years later nothing was left and all that remains of unemployment insurance today is its name. Now the welfare principle is applied for the unemployed: insurance allowance without examining the necessity, namely, with legal rights for six weeks only. Juveniles and working women have no legal claim.

The period for which benefits are made must of course be limited, as with a subscription of $6\frac{1}{2}$ per cent of their wages not all unemployed can be supported. The greater the number of unemployed the lower the limit must be set. At first the allowances were made for 26 weeks, now for 6 weeks. As in this crisis unemployment frequently lasts for years, most of the unemployed no longer receive any allowance. The unemployed insurance at present scarcely supports one-third of the army of unemployed while the other part is supported by the welfare and the crisis centres. The same was the case before social politics had their "crown" put on. These institutions draw their funds from the State revenues.

Thus the communes had to bear the chief part of the burden the same as before. It is a curious fact that the communes tried to cast off the burden by finding work for part of the unemployed, until the latter had paid their premiums into the unemployment insurance, thus gaining a fresh legal claim. Then the same thing could begin all over again.

That is the curse of the evil done by trying to force something into insurance formulas that is uninsurable.

Sick Days Jump from $5\frac{1}{2}$ to 28

It is not in the least different with the sick insurance. The unevenness in the business level, the seasons, holidays, a change of work, failing health and many other

things contribute to bring about a noticeable change in morbidity.

Since the sick insurance has been in effect, the average number of days of incapacity to work owing to ill-health, has risen from $5\frac{1}{2}$ to 28 days, although health in general has considerably improved.

In the strict sense of the word the sick insurance is no insurance either. From a technical and mathematical standpoint it is also quite unsettled in view of the moral hazard noted above.

This is clearly seen when considering that the individual insurance case, whether due to illness or unemployment, can be willfully caused or extended. Where is the border line between illness and health, between mere indisposition and illness, between dread of getting ill and bluff? And if the insured person is really ill, where is the border line between ability or disability to work? How can the duration of an illness be fixed?

Illness is the most incalculable risk in existence.

Even the doctor is mostly, or at least frequently, unable to diagnose correctly and to distinguish pretenders and hypochondriacs from really sick people, or rather to tell whether a man is fit to work or not.

"Hazy and Uncontrollable"

The same stands for unemployment. It can be ascertained if and when a man lost his job, but not whether he refuses work that is offered him—maybe because the work does not pay well enough; or whether he does odd jobs and thus finds other sources for earning money.

Also, the degree of diminished ability to work, due to an accident, can only be guessed at.

Of all the risks in social insurance only old age, death, and number of dependents can be exactly established. These are therefore the only cases in which an unobjectional actuarial basis, and an unquestioned legal claim are possible. Everything else is hazy and uncontrollable.

And on this unstable foundation was based a legal "claim"! Thus in millions of cases, wrong was turned into right and the gates opened wide to fraud.

A House Built on the Sands

I can here speak only briefly of these things. Additional material may be found in my books:

GERMAN

"Irrwege der deutschen Sozialpolitik," Scherl, Berlin, 1928.

"Die Nationalsozial Revolution, die Lösung der Arbeiterfrage," I. F. Lehmann, München, 1932.

ENGLISH

"Bankbook Instead of Alms" (will appear shortly).

What is decisive in judging the merits or the worthlessness of social insurance is not brilliant theories interspersed with sentimentality and false humanitarianism, but the rougher language of practice. A few words on that subject:

The sick insurance provides the workman with medical attendance free of charge, with medicine and other necessities, and with an allowance.

Anyone will at first sight consider this a great blessing for the workman as well as for national health. The reality, however, is very different.

A Nation of Valetudinarians

Dread of illness obsesses most people and this has been pressed into a system "illness made easy" by which the will to be well is strangled. The doctor is consulted a dozen times where once would be sufficient—the insurance pays. The prescribing of medicine, bandages, etc., is desired. When they have been obtained they lie about until they are no longer fit to be used and must be thrown away—the insurance pays. Besides it is nice to get something in return for the premiums paid year in and year out. Excessive "overdoctoring" is the result and fear of illness that shakes the will for recovery—the best aid to health. Pretenders and hypochondriacs are bred and the use of medicine becomes excessive. The advertising of certain remedies and cures created a medicine craze. A few years ago it was ascertained that four times as much money was used for doctors' fees and medicines for 35,000,000 of people in insurances as for 30,000,000 of uninsured. This was stimulated, unthinkingly, by a desire to get sick money. An actual run on the sick insurance allowance set in.

At first sight it seems improbable and paradoxical that a desire to obtain sick money that scarcely amounts to half the sum of wages should arise. It appears impossible that someone should, unless compelled by illness, forfeit his wages to get an allowance of half the amount. Unfortunately life does not run a straight

course between health, working ability, working possibilities on one hand, and illness and disability on the other, nor do people's minds and actions.

When Sick Benefits Come in Handy

In millions of cases, for example, when wages are being decreased, when work is scarce and work hours in consequence shortened, when there are fewer shifts, many holidays, work restrictions at certain seasons, outdoor work in frosty weather, 50 per cent of the wages is welcome. One objects to the work he is given, another does not feel like working, a third's time is taken up by some family matter for which he would have to take leave of absence and forfeit his pay. In such cases the sick insurance comes in handy. Besides this, there is also deceitful trickery. Fictitious contracts are made, doctors are induced to prescribe medicine and instead of the medicine toilet soap and scent, etc., are handed out by the pharmacies.

Doctors Driven to Mass Practice

How can this possibly be done? some ask. Those who consult doctors are supposed to be ill. That is all very well if the doctors were always able to detect whether the statements of the patients were correct. Often a diagnosis is impossible. He who would like to prove this should go to ten doctors, complain of headache, pain in the limbs, rheumatism. All ten will start a treatment for headache or rheumatism, without discovering that nothing whatever is the matter with the patient.

Besides that, all doctors are glad to get new patients, for do they not mean their livelihood?

Medical science has become a cheap article, and doctors have given up conscientious treatment. The genuine patient is neglected, is not given the necessary care.

The greater the mass consultations, the lower are the doctor's fees. The amounts paid to panel doctors for each single case are deplorable. They are therefore compelled to resort to mass practice.

The sick insurance unrolls the entire problem of the medical man's existence.

Mass demand compelled a limitation in the use of medicines. Doctors must not prescribe what they consider good for the patient, they only being allowed to give remedies entered in a book of medical regulations for insurance purposes.

The insured workman becomes a second class patient.

Wages Without Work Kill Thrift

Wages without doing any work—that is what the unemployment insurance amounts to—create in course of time aversion to work, and destroy the instinct for thrift.

Two years after the unemployment insurance came into force a member declared on the floor of the Reichstag, "Those who draw money from the unemployment insurance consider us fools."

A high government official proved that experience had shown that one-third of those drawing unemployment money were devoid of any sense of what is social, and that in one town of his district 43 per cent refused to take any job offered them.

A network of deception has been spread. Farmers exchanged sons, registered them as workmen, so that they might get the insurance in winter for both families.

Fictitious work contracts were made, and with illicit work a system of deception was established. Unemployed workmen getting their allowance, snatched work away from artisans and businessmen, etc., as, owing to the allowance, they were able to do the same work for less pay than honest workers who had to pay rates and taxes. Employers engaged workmen for half wages without registering them, and paid neither wage tax nor social insurance premiums, and the "unemployed workman" pocketed his "allowance" besides.

Raids on "Illicit" Workmen

Since last year police raids are occasionally made in the big cities in search of illicit workmen in market halls, ports, at railway stations, etc. Thousands were caught, part of them were imprisoned.

Bluff is used for cheating the accident insurance. The casualty hospitals are called "bluffer universities."

All meeting with an accident try to represent the injury received worse than it is in order to obtain a higher allowance.

Certain methods of medical treatment were forbidden as they could not possibly have the desired effect, the patient not having the wish to get well and to forfeit the allowance.

The annuity, old age, disability insurances have introduced a treatment for strengthening delicate patients, so that they need not start payments too soon.

Holidays Now Taken on Sick Insurance

In the first months of the year the applications for cures to the disability and employees insurances pour in because many are anxious to take their summer holiday at the expense of the social insurances.

Matters soon made an extensive controlling system necessary. This ended in badgering all persons concerned.

Patients are visited in their homes by controlling officials who have to convince themselves that the patient is really ill and not doing any work. The patients are therefore allowed certain hours for going out by the doctors.

The sick insurance engages so-called confidential doctors who have to submit the patient to a final examination to see whether he is too ill to work. The results of such examinations are to a great extent startling. Here is one instance from among thousands: 2008 patients were ordered to appear for a final examination. Eight hundred sixteen of them at once declared their complete recovery; 289 were found to be well by the confidential doctor. So nearly 50 per cent were not ill at all.

Medical Policemen Now

The confidential doctor is, so to say, the medical policeman, who not only controls the patients but also his fellow doctors who are treating them.

The genuine patient is justly indignant to find that the existence of his illness is doubted, and that he who has always paid his premiums regularly and has a right to demand conscientious attendance, is considered a cheat.

This system, together with the rest of the bureaucratic apparatus, has wedged itself between doctor and patient, completely destroying the patient's confidence in his physician, which greatly retards all recovery.

The sound idea of sick insurance has become thoroughly unsound, and the harm it does far outweighs its advantages.

In the unemployment insurance the controlling is done by making the workmen have a stamp put on their premium card once a week. How defective this method is, is proved by the problem of "illicit work" and the police raids for illegal workers.

I once stated in a lecture that I knew the way of quickly diminishing the number of unemployed by 50 per cent: the state was to enlist half of the army of unemployed as auxiliary policemen to shadow

the other half. This would be effective control provided that there were no secret understandings between the shadowers and the shadowed.

Pronounced Well, but Dies Two Days Later

In any other way control is ridiculous. Those who know anything about medical certificates; those who know that in ninety-nine cases out of one hundred they contradict each other, and who also are aware that medical opinion forms the basis for the amount granted by the accident insurance as well as for the sickness and disability allowances can easily imagine what happens. They will not be surprised that a confidential doctor whose task it is to keep the number of patients low, declares a patient recovered who nevertheless dies two days later.

The connection between the different risks in the social insurance system is of much more importance than would at first appear.

So the so-called occupational diseases (twenty-two of them) are classed as accidents and passed on to the accident insurance.

Annuity insurance takes upon itself the medical treatment that really ought to fall to the sick insurance, whereas the sick insurance pays sick money for twenty-six weeks only. If the illness lasts longer, the disability insurance has to pay. On that account twilight zones and certain legal relations exist between the different branches of social insurance.

Were there only one insurance all responsibility would be loaded upon it. Until the unemployment insurance existed all who were dismissed from their jobs reported as patients to the sick insurance to obtain the sick insurance allowance.

Welfare Remedy for Every Ill

We find that the extension of social insurance takes on an automatic tendency. As long as there was no unemployment insurance, the sick insurance formed the best barometer for the state of business. When social insurance was first planned in Germany, accident insurance only was considered. Accidents not being of frequent occurrence, relatively few workmen met with accidents. When the sick insurance was made compulsory, many more accidents occurred. These accidents were not reported as accidents, but as sickness. These accidents were not reported as accidents, but as sickness. These accidents were not reported as accidents, but as sickness.

Bismarck considered sick insurance a supposititious child, it was the first to be enacted.

When the world depression set in, the time seemed to be ripe for unemployment insurance.

When, during the last few years, the sinking birth rate pushed the problem of population into the foreground, the introduction of a mother-and-parenthood insurance was seriously discussed.

In the beginning nobody thought of insuring all workmen, merely needy ones. But soon everybody was "needy." Today, with members of families included, two-thirds of the nation are compelled to be insured.

Goal Is to Make All People Pensioners

A pension and support craze has been fostered that aims to make the entire population of the country state pensioners, relieving the individual thereby of the duty of caring for himself, and of saving.

State pensions mean the death of all will to work and of all personal ambition.

Liberty and progress are possible only where the will to get on and to accumulate capital is not hindered, but furthered.

Social insurance has produced an unbelievable number of questions and problems hardly fathomed by the uninitiated, who face them quite helplessly.

Practice alone gained by fifty years of experience can answer these questions.

What is given here is merely a few outlines.

It is impossible even to mention all doubts in a short paper such as this, far less to answer them explicitly.

From what has been said it can however be clearly seen that social insurance is no simple matter but an extremely intricate problem.

Mushroom Growth of Laws and Administrators

Therefore a few lines about laws and administration. Social insurance laws consist of 2700 paragraphs, 200 of these have lately been abolished. A great number of amendments, executive regulations and alterations supplement this confusion of paragraphs. Even experts can only make them out in parts.

By extending and employing these paragraphs another tangle of commentaries has grown up around them. To an ordinary mortal this work is a book with seven seals. Nor could it possibly have been simplified.

As soon as such a law has been made, flaws are detected. These must again be rectified.

Ever since social insurance has existed, it has been subjected to reforms, one following the other in rapid succession.

Legislation is never done with social insurance. In keeping with its complexity, its expansion, and its millionfold ramifications in the life of the state and the people, is the size of its organization and its administrative apparatus.

The Growth of Bureaucracy

The number of officials required for the administration of social insurance varies in accordance with the amount of work being done. In total, and including the unemployed, 22,000,000 is the approximate number of insured persons.

There are about 6500 sick insurance units. Unemployment insurance is administered from one National institute, which controls thirteen state centers and 361 local centers.

The premiums for the unemployment insurance are collected by the sick insurance.

The accident insurance is administered by 66 trade organizations with 261 sections and 40 agricultural organizations with 526 sections.

The disability and old age insurance is managed by 29 regional "Landesversicherungen" (Offices of the provinces) and 6 special institutions.

One of these is the Reichs-institute for clerical employees and the Reichs-miners' insurance office with 16 district offices.

Billions of Premiums Never Reach Goal

During the last few years the administration costs amounted to 400 million marks annually. The costs cannot be called too high and cannot possibly be materially reduced.

However, the whole matter gets another aspect in view of the fact that these expenses are covered by workmen's premiums and are deducted year by year from the money intended for these men's support. In one worker's generation—say from the age of 20 to 60, or 40 years—it means the gigantic sum of 16,000,000,000 marks, which therefore is lost from the funds originally intended for sick, unemployment and old age insurances.

An army of about 70,000 officials is

required to handle part of the wages of the workers under compulsory administration, for what else is social insurance?

For every 200 workmen one official is wanted in the above-mentioned administrative apparatus, which by no means comprises the entire machine. A great part of the administrative body is borrowed from other departments of government, as for instance the Reichs-post office, as well as private business concerns. The post office sells the premium stamps and pays out annuities for the old age insurance.

Wage Computation Has Become a Science

The private business concerns serve as collecting agencies. Their duty is to compute the premiums, to deduct them from the wages and to convey them together with the employer's share of the premiums to the different offices of the social insurance. The wage departments therefore have become unduly enlarged, causing considerable extra cost which is hard to account for. Wage computation has gradually come to be a science in Germany.

But that is not all.

The extension of the administration, its multiformity, the complication of its legal regulations, requires a special supervising and judicial staff. This work is accomplished by a Reich-insurance office, 3 regional insurance offices (these are now going to be closed down), 68 head offices and 1100 insurance offices. The costs for this army of officials are not included in the administrative expenses, but are borne by the State—also the administrative expenses of welfare relief, which has provided for the majority of the unemployed lately.

Palaces for Bureaucrats

What gigantic sums of the workmen's capital is invested in the buildings in which the offices are housed can be calculated from the figures of the administrative apparatus. In many towns the buildings of the social insurance are the largest in the whole cities. In the period 1918 to 1932 particularly, so much money was invested in these palatial buildings that it resulted in a public scandal. The sick insurance palaces and the unemployment office buildings vied in size and splendor with the administrative palaces of great financiers and industrial concerns, or representative public buildings. In many places they even outshone them. While many workmen are

living in dilapidated houses, their money was used for building huge, luxurious offices, which bore no sign of their purpose being the administration of the hard-earned capital of the working classes, put by for times of need.

To these must be added numerous other buildings: laboratories, dental stations, medicine depots and a considerable number of nursing homes (the latter must not be confounded with the many hospitals, sufficient in number, clinics, etc., belonging to the State or universities, towns, religious organizations, co-operative organizations, etc.). The incalculable sums invested in these buildings and their luxuries can never be converted into allowances for the support of the needy.

Scandals of Administration

Downright corruption adheres to the palaces. One scandal follows the other. Administration officials, suppliers, architects were dragged into the mire. Common embezzlement, bribery and other dishonorable acts on the part of officials were uncovered. Excessive squandering of money, doctors, dentists, chemists, even employers were involved, the latter chiefly as wilful premium defrauders. They had deducted the premiums from the workmen's wages without paying them to the insurances. To this came the unnecessary, dishonest exploitation of the insurances by pretenders, annuity chasers, illicit workers.

All this at the workmen's expense, for the part of the premiums supposed to be paid by the employer is in reality borne by the workmen, either as consumer or as wage earner. The idea of burdening the employer with part of the premium is good and sound, but only as long as it was low. Today the employer's share is about 10 per cent of the wages and in consequence one of the most vital expense items of the economic system. As the employer's premium share is immediately connected with the wage, it is shifted over on the wage.

Wherever It Comes from the Workman Pays

In Germany no one any longer doubts the fact that the employer's share of the premium is taken from the workman's wages. What the employer pays as his contribution to social insurance, he cannot pay the workmen in the form of wages.

Some years ago a well known trade

unionist even had to admit that countries without social insurance have higher real wages than Germany (United States of America, Holland, Scandinavia) while another said: "high wages are the best social policy." In other words, social insurances handicap wage development. But not only this, they also intensify wage struggles.

Premiums started on a modest basis. The first were $1\frac{1}{2}$ per cent for the employee and $\frac{3}{4}$ per cent for the employer. Today, the entire premium averages almost one-fifth of the amount of the wages and for miners it is nearly 30 per cent. The involved way in which the contributions are divided between employer and employee is omitted here, as an alteration is pending. It is expected that employer and employee will in future bear equal share, about 10 per cent each. Is it to be expected that an employer can afford to make an employee a present of 10 per cent in addition to his wages?

Intended Cure Proves Rank Poison

The only part of the wages he might be able to save in order to build up a capital is taken from him, thus preventing him having any resources of his own. Whether he wants to or not, he is doomed forever to remain a proletarian.

It is social insurance therefore that makes needy people, in order to give them after they have become needy, very inadequate support. Social insurance originally was established to help those in distress. Now there are poor of its creation.

The assertion that social insurance increases poverty, making it an everlasting doom from which there is no escaping, a fate accompanied by discontent and despair, is evident. It becomes clearer still at sight of a few figures. I do not take one-fifth but the lowest average figures now valid in Germany—17 per cent of the wages. The result is the yearly premium amount, as shown in the table.

Weekly wages....	20,-RM	[\$5.00]	25,-RM	[\$6.25]	30,-RM	[\$7.50]	40,-RM	[\$10.00]
Yearly premium...	177,-RM	[\$44.25]	221,-RM	[\$55.25]	265,-RM	[\$66.25]	354,-RM	[\$88.50]
Weekly wages	50,-RM	[\$12.50]	60,-RM	[\$15.00]	70,-RM	[\$17.50]		
Yearly premium...	422,-RM	[\$105.50]	530,-RM	[\$132.50]	609,-RM	[\$152.25]		

Welfare Dollar Can't Be Wage Dollar

Certainly not. He keeps it in mind when fixing wage rates. Of the part of the premium an employer pays, the workman hears and sees nothing and still the amount is deducted from the gross amount of his wages. He can only reckon with the net wages which have been shortened by 20 per cent. Consequently the wages always appear too low. On the other hand, the social burdens have always been a handy excuse for the employers, even when wage demands were fully justified.

Must not this intensify wage struggles? Anyone can imagine the feelings of a workman, who week by week, month by month, year by year, suffers a compulsory loss of one-fifth of his earnings. This loss of a considerable part of his wages really means expropriation.

Juvenile workers start paying at the age of 14 and 15 and go on paying until the age of 65, or until completely disabled.

Must the idea not arise that a workman should be allowed to keep his own savings and to invest them at interest, so that he may be able to keep himself and his family in the time of need out of his own means? This idea becomes more concrete, when we consider in what way the sum, if properly invested, might increase at an interest of 5 per cent which still seems adequate in Germany.

Less Management, More Pay

In the accompanying table are the results supposing that payments are made continuously and nothing withdrawn, between the ages of 20 and 65 years, for a workman with a weekly wage.

20,-RM	[\$5.00]	25,-RM	[\$6.25]	30,-RM	[\$7.50]	40,-RM	[\$10.00]	50,-RM	[\$12.50]
28,000 Rm		36,000 Rm		43,000 Rm		56,000 Rm		77,000 Rm	
	[\$7,000]		[\$9,000]		[\$10,750]		[\$14,000]		[\$19,250]
60,-RM	[\$15.00]	70,-RM	[\$17.50]						
86,000 Rm		100,000 Rm							
	[\$21,500]		[\$25,000]						

Even if calculating at low interest as the basis, the figures reached will be enormously high. For a calculation covering 45 years, neither very low nor very high interest must be taken, but a medium one.

It must, however, also be considered that these figures only refer to one member of the family, that most workmen have a wife, who before marriage worked and paid insurance premiums, too, that many of them

GERMAN PAY ENVELOPE

It shows actual deductions from the weekly wages of a workman. The average over the whole country is 20 per cent of the pay. In some instances, it amounts to 30 per cent. Mr. Hartz points out that it makes no difference whether the assessment is deducted from the wage of the employee or whether the employer puts it in for him. The workman pays it in either case, since a mark paid out by an employer in social insurance premium is obviously a mark that cannot be paid out in wages

go on working, when they are married and pay premiums, and that the children at the age of 14 or 15 start paying also.

A Newer Plan—Compulsory Savings

Only then is it possible to realize how the workman's family is pauperized by insurances.

Though such proofs are only of theoretical value, they clearly demonstrate that there is no necessity for men to remain proletarians forever; that they need not allow themselves to be forced into the straightjacket of collective mass insurance and that on rare occasions only they need be obliged to resort to help from others.

The proposal has therefore been made to substitute for social insurance, which has so many unavoidable drawbacks, a system of social savings accounts, each workman banking for his own account. Then, in case of illness, unemployment, etc., he would be able to fall back upon his own resources first of all.

In the same manner as the workman is now compelled to pay premiums for social insurances, he should be obliged by law to make regular deposits into his savings account.

This would be the duty of the State, as in cases of distress of great dimensions, providing for the poor would fall to its share. Under a social insurance system, the number of people who, when they have no earnings must be supported, is constantly increasing, while the number would diminish if people were forced to save.

Trend Would Be Toward Independence

A State that has to take the responsibility of providing for the majority of its subjects, as is the case with social insurance, is bound to collapse when the time of need comes.

Every single individual should be made to see that he has the duty to provide for himself.

Independence and a sense of responsibility of the citizens are the only means to save a State from too great a social burden, as was the case in the United States before the great crisis came. There the inexorable "I must" drove everyone on, for no social insurance existed to take the trouble from the people in a time of reverses.

But every nation has a great number of subjects for which a compulsion, it only being a moral one, does not suffice. They have not enough will-power of their own to put by sufficient of their earnings for a

rainy day. Besides this there are others who rely on their luck and, trusting in everlasting prosperity, live carefree lives, forgetful of times of distress.

Only Felt By Ne'er-Do-Well

These carefree, weak characters are the ones that require State compulsion. For them laws are a necessity—also in consideration of the others who would be burdened with the care of them. For the strong-minded the compulsion is merely the fulfilment of what they themselves consider a natural duty. Therefore it does not mean compulsion for them. A duty to save, prescribed by the State, is the best solution of this problem. All this can be carried out with the means which are now wasted for social insurance.

Instead of an insurance card the workman would have a bank book, the best way of giving him a sense of responsibility.

For the carrying out of this no new institutions would be required. The existing banks and credit institutions together with the postal saving banks or similar institutions would suffice.

The administration costs would not be drawn from the deposits, as in the social insurance from the premiums, but would support themselves the same as in all banks, from their own profits. On the contrary, the savers would be paid a normal percentage of interest besides.

Here the State would only have a suitable control and regulations for the investment of the capital as, for instance, it has in German savings banks.

Right of Inheritance Remains

These savings must of course only be used for the social purposes they are intended for, and must be blocked until a certain amount has been accumulated.

These restrictions are very slight indeed compared with the entire loss of disposal rights under a social insurance system, for here the property rights as well as the rights of inheritance remain, which is not the case with any of the social insurances.

All waste would disappear, all control might be abolished when men no longer ate out of a large common dish but had to pay for everything out of their own pockets.

The administration of social saving banks can be made quite easy and simple.

The calculation of the wages would no longer be complicated, and the amount of

the employer's premiums would no longer be camouflaged and deducted from the workmen's wages. The workers would get the full amount of their wages, but part of them in form of a bank credit. Details it is not the place to discuss here, but that this method is easier to carry out than that of the involved social insurance is evident. The laws required would not need more than one-tenth of the paragraphs of social insurance.

Five Per Cent Helpless, as Against 66 2/3 Per Cent

Those few who, under a savings account system, might fail to be able to support themselves (it should not exceed 5 per cent of the entire number) must of course be taken care of by society. That they could be cared for better than when all are obliged to rely on public help, stands to reason.

Existing institutions for the aid of the poor, trade unions, voluntary welfare organizations such as the Salvation Army, Red Cross, and other charitable institutions, etc., would be quite sufficient. This work might also be regulated and supervised by the State. Flexible support which depends on the extent of the distress and the requirements in each individual case, is more social than the so-called help of social insurance, which adheres rigidly to regulations and paragraphs.

Social insurance is distinctly a system that eats up and wastes capital. If it were based on adequate capital and reserves, the premiums would be so high that there would not be enough money in the world to pay them.

It has been proved that State social insurance saps the supply of capital required by private life insurance. A workman with savings of his own can insure his future by insuring his life.

Plan Affords Greater Flexibility

The saving system is not only a systematic accumulation of capital, but it distributes capital in the broadest way all over the nation.

An economic crisis is largely aggravated by the fact that the middle classes suffer most, which means that the consuming power of a broad section of society is impaired.

Under the savings system the larger part of the working population can, within a generation, be raised to the level of middle class

prosperity. But even in the very beginning, when the broad masses notice the growth of their savings accounts, their minds will be imbued with the sense of property ownership and capital formation. Thereby an objective will be set which they will try to reach and which will stimulate their ambition.

This forms the safest bulwark against the encroachment of communistic-socialistic ideas.

Up to Middle Class in One Generation

With a social insurance for wage earners only class distinctions are legally sanctioned and more and more aggravated.

All classes could, up to a certain income and fortune limit, be included in the savings system without there being any danger of a general State pension complex.

One might easily be led to think that in times of great distress, such as the present crisis, the introduction of a savings system would be impossible. If that were so, the establishment of social insurance must be all the more impossible. If millions of unemployed have neither capital nor an income to live on, when hundreds of thousands of members of the middle classes are impoverished, the first endeavor must be to prevent more people from falling to the care of the State, to stop poverty increasing, and to make up for losses sustained with utmost speed.

Unemployment Insurance Not for Idle

If unemployment insurance is not introduced until millions are already out of work, the unemployed cannot be taken care of by the insurance, because, under any insurance system, a claim for an allowance must be preceded by payment of adequate premiums over a stipulated period (six months in Germany). Unemployment insurance is therefore only for those who are still in work but may be unemployed later on.

For the employed there is always the possibility to make deposits against a possible need and thus to erect a bulwark against further demands on public aid. The introduction of social insurance expects exactly the same from them.

Social insurance has taught one good lesson: every one must use part of his earnings to protect his future.

Times of unemployment can be bridged over from earnings and from them only.

Why, people will ask, does Germany after having experienced the great draw-

backs of social insurance, not adopt this system—a system that seems so reasonable and so full of appeal to human nature?

If Germany had no social insurance system, but still had her 50 years of experience in it, she certainly would not adopt social insurance today.

But it would now mean in Germany transforming one system into another. And this is where the difficulty lies.

Irrevocability of Welfare Laws

When a nation has been swayed by a certain law for half a century, this has, be it right or wrong, entered into its mentality and it would be a difficult task to train a nation to another way of thinking.

Added to this, a colossal institution such as the German social insurance is bound up in the State's national and economic life, and, besides, an army of people—direct or indirect—live on it.

And what is more vital still is that millions of old people, of disabled, widows, orphans, cripples, depend for their very existence on the insurances, and that many millions through contribution over decades have gained rights that at any cost must be respected.

Although ways and means for a change might be found, the winding up of the present system would require a very long time—for the annuity insurance it would take years. This is clearly to be seen when we learn that for the covering of existing claims in the annuity insurance,

16,000,000,000 marks are wanting. Payment does of course not fall due today or tomorrow. It extends over a long space of time. But still the means have to be found.

From what has been said here it may be seen that social insurance, once established, is difficult to abolish. This ought to be borne in mind and be a warning to take particular care and consider it well.

Slate Here Comparatively Clean

For a State not burdened with the obligations of social insurance the introduction of the saving system is easy and without any risk, as the State has not to take upon itself the legal obligation to provide for those unable to do so for themselves.

For the new German government the most vital thing was to prop and support the gigantic structure, to prevent its collapse and thereby to safeguard the existence of millions. The Augian stable of corruption has been cleaned and reforms introduced. What the result will be, how matters will further develop, remains to be seen.

One thing however is certain: there is only one State in the world that fights proletarianism among the working classes energetically and purposefully with all ideal means, and in principle shares the opinions expressed here—that is Germany. In what way the ideal and material raising of the proletariat will develop depends on the economic development of the next few decades.

ADMINISTRATION BUILDING OF THE INSURANCE FUND FOR EMPLOYEES, BERLIN

OBSERVATIONS ON ARSPHENAMINE DERMATITIS

With Special Reference to the Reliability of the Patch Test

JAMES W. JORDAN, M.D., AND EARL D. OSBORNE, M.D.

*From the Department of Dermatology and Syphilology, Buffalo General Hospital,
Service of Dr. Earl D. Osborne.*

Most modern authors (Stokes,¹ Moore,² Bloch,³ Wise and Sulzberger,^{4,5} Schoch,⁶ and others) believe that arsphenamine dermatitis represents an allergic phenomenon. As a result of this concept, investigators have attempted to apply skin testing methods, of value in other allergic diseases, to the problem of arsphenamine dermatitis both as a diagnostic procedure and as a guide to further treatment.

The value of such methods is still a debated question. Mook,⁷ in 1920, first attempted to demonstrate hypersensitivity to the arsphenamine in a case of post-arsphenamine dermatitis by the scratch test method, with negative results. Later, Moore and Keidel,⁸ had similar results with the same method. Klauder⁹ obtained positive scratch tests to arsphenamine and neoarsphenamine in a patient who had a contact dermatitis due to handling the arsphenamines and asthmatic symptoms from inhalation of the drug.

Stuart and Maynard¹⁰ were able to demonstrate hypersensitivity to arsphenamine in 2 of 3 cases of post-arsphenamine dermatitis by the intradermal method. Moore, Woo, Gay and Robinson,² using a similar method, found that 70 per cent of patients, who had had a severe post-arsphenamine dermatitis, exhibited hypersensitivity to the drug, and 95 per cent of patients, 18 of 19 cases tested, who were sufferers from hay-fever without any dermatitis, also gave positive tests. Cannon and Karelitz,¹¹ in a recent report, found strongly positive intradermal tests in only 48.7 per cent of cases of post-arsphenamine dermatitis and also obtained positive tests in patients suffering from dermatoses other than arsphenamine dermatitis.

Work has also been done on cutaneous reactions to patch tests with the arsphenamines. Chargin, Sulzberger, and Crowley,¹² using patch tests of 10 per cent neutralized arsphenamine, found that of 210 syphilitics with no dermatitis, 17 per cent reacted positively, and of 293 normals, 21 per cent reacted. Only approximately 2 per cent of this entire group gave strong

positive reactions. They were unable to establish any relationship between the positive tests in syphilitics and the development of arsphenamine dermatitis when the drug was later administered.

Schoch,¹³ using a 33⅓ per cent neoarsphenamine solution, tested 50 syphilitics, 46 normals and 4 persons who had had a previous severe arsphenamine dermatitis. Only the 4 persons who had had a dermatitis reacted with strongly positive tests.

Later, Schoch⁶ reported 8 cases of post-arsphenamine dermatitis of varying grades of severity. Four of the 8 gave strongly positive patch tests to 33⅓ per cent neoarsphenamine and upon further administration of small doses of the drug developed mild recurrences of cutaneous symptoms. The remaining 4 gave negative tests. Further administration of the drug was tolerated without incident. On the basis of these observations, Schoch strongly recommended the patch test method to determine if further treatment with arsenicals could be safely attempted.

Moore,¹⁴ in his recent textbook commenting on Schoch's work, states that he has seen negative patch tests in patients known to have cutaneous intolerance to the intravenous administration of the arsphenamines.

Through the work of these investigators, it is apparent that scratch tests and intradermal tests are of limited value in determining the existence of a state of cutaneous allergy to arsphenamine products. Tests may be negative when cutaneous intolerance exists or nonspecific positive tests may be obtained in the absence of dermatitis. The intradermal test has furthermore been frowned upon because of the possibility of inducing a state of cutaneous allergy where none previously existed. Frei,¹⁵ Sulzberger,¹⁶ and others have been able to produce cutaneous allergy in guinea pigs by intradermal injections of arsenical preparations. The value of patch tests is subject to controversy. Schoch strongly recommends the method. Moore feels that it is not a safe method in determining the existence of cutaneous allergy.

Materials and Methods

The present study was made of 12 patients who had had post-arsphenamine dermatitis of varying degrees of severity and of 135 patients under active treatment for syphilis who had shown no cutaneous intolerance to the drug. Patch tests of 33⅓ per cent neoarsphenamine were applied to the inner side of either arm and allowed to remain *in situ* for 24 hours. Readings were made at the time the tests were removed and at the end of 72 hours. Only strongly positive reactions were considered significant. Tests were considered strongly positive when the test site showed erythema and vesiculation. All of the patients who had shown previous evidence of cutaneous intolerance to arsenicals were placed on gradually increasing amounts of arsphenamine or silver arsphenamine in an attempt to discover, first, whether cutaneous intolerance to the drug persisted and, second, if the intolerance was accurately foretold by patch test methods. The 135 patients who had not had a previous cutaneous accident were permitted to continue antisyphilitic treatment regardless of patch test findings. It was found convenient to divide the patients into four groups and to summarize their findings in Charts I to III.

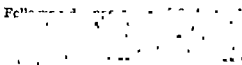

Chart I summarizes the findings of 5 patients who had had a severe arsphenamine dermatitis of three weeks' to two months' duration.

Chart II summarizes the findings of 7 patients who had had a mild arsphenamine dermatitis of two days' to two weeks' duration.

Chart III summarizes the findings in 5 cases found to have strongly positive patch tests out of the group of 135 patients tested. These patients, at the time the tests were applied, were under routine treatment for syphilis and none had had an arsphenamine dermatitis.

The accompanying charts demonstrate that the patch test is not a reliable guide to further treatment with the arsphenamines following an arsphenamine dermatitis. First, tests may be negative or only faintly positive when cutaneous intolerance to the arsphenamines exists (Chart I, cases 3, 4, 5). The explanation for this is not clear. It is generally believed that when a dermatitis is eczematoid in character the epidermal cells themselves are sensitized and perhaps also the blood vessels of the upper corium (Bloch,³ Wise and Sulzberger,⁴ Sezary and Mauric²⁰). It is logical to expect an allergic reaction (positive patch test) when the antigen in sufficient amounts is brought in contact with the sensitized epidermal cells. It has been pointed out by Wise and Sulzberger that this is the case in analogous drug eruptions, *i.e.*, quinine, formalin, etc., where the sensitizing substance has been taken internally and the antigen carried along by the blood stream to sensitized

CHART I—ARSPHENAMINE DERMATITIS

Cases 1-5			Severe Types — Vesicular				
Case	Age	Sex	Treatment before onset of dermatitis	Type of dermatitis	Duration	Patch test	Remarks
1	43	M	13 arm injections Drug? Dose?	Severe vesicular	2 months	1 yr. later, strongly pos	 0.3 gm. by error. Recurrence severe dermatitis
2	52	F	1 arm injection Drug? Dose?	Not seen	6 weeks	4 yrs later, strongly pos	Given 1 inj arsph. 0.009 gm. Caused mild generalized erythema with itching.
3	33	F	6 injections arsph. 0.3 gm.	Severe vesicular	1 month	2 months later, neg	Given 1 inj arsph 0.009 gm. Caused mild generalized papulovesicular dermatitis
4	19	F	3 injections arsph. 0.3 gm.	Severe vesicular	1 month	2 yrs later, slightly pos.	Given 1 inj arsph 0.1 gm. Caused mild generalized papulovesicular dermatitis
5	17	F	2 injections arsph. 0.2 gm.	Moderate vesicular	3 weeks	6 mo later, negative	Given 1 inj. arsph. 0.3 gm. Caused generalized moderately severe dermatitis.

OBSERVATIONS ON ARSPHENAMINE DERMATITIS

With Special Reference to the Reliability of the Patch Test

JAMES W. JORDAN, M.D., AND EARL D. OSBORNE, M.D.

*From the Department of Dermatology and Syphilology, Buffalo General Hospital,
Service of Dr. Earl D. Osborne*

Most modern authors (Stokes,¹ Moore,² Bloch,³ Wise and Sulzberger,^{4,5} Schoch,⁶ and others) believe that arsphenamine dermatitis represents an allergic phenomenon. As a result of this concept, investigators have attempted to apply skin testing methods, of value in other allergic diseases, to the problem of arsphenamine dermatitis both as a diagnostic procedure and as a guide to further treatment.

The value of such methods is still a debated question. Mook,⁷ in 1920, first attempted to demonstrate hypersensitivity to the arsphenamine in a case of post-arsphenamine dermatitis by the scratch test method, with negative results. Later, Moore and Keidel,⁸ had similar results with the same method. Klauder⁹ obtained positive scratch tests to arsphenamine and neoarsphenamine in a patient who had a contact dermatitis due to handling the arsphenamines and asthmatic symptoms from inhalation of the drug.

positive reactions. They were unable to establish any relationship between the positive tests in syphilitics and the development of arsphenamine dermatitis when the drug was later administered.

Schoch,¹³ using a 33⅓ per cent neoarsphenamine solution, tested 50 syphilitics, 46 normals and 4 persons who had had a previous severe arsphenamine dermatitis. Only the 4 persons who had had a dermatitis reacted with strongly positive tests.

Later, Schoch⁶ reported 8 cases of post-arsphenamine dermatitis of varying grades of severity. Four of the 8 gave strongly positive patch tests to 33⅓ per cent neoarsphenamine and upon further administration of small doses of the drug developed mild recurrences of cutaneous symptoms. The remaining 4 gave negative tests. Further administration of the drug was tolerated without incident. On the basis of these observations, Schoch strongly recommended the patch test method to determine if further treatment would cause recurrence of dermatitis.

8 mos. later, negative	Given 7 inj. arsph. 0.3 gm. No recurrence of dermatitis.
4 mos. later, negative	Given 4 inj. arsph. 0.05, 0.05, 0.1 gm., 1 inj. silver arsph. 0.2 gm. No recurrence of dermatitis. Treatment stopped because of gastro-intestinal reactions.
8 yrs. later, negative	Given 4 inj. arsph. 0.2 gm. No recurrence of dermatitis. Treatment stopped because of gastro-intestinal reactions.
1 yr. later, negative	Given 5 inj. arsphenamine 0.3 gm. No recurrence of dermatitis. Treatment stopped because of gastro-intestinal reactions.

9	25	M	10 injections arsphenamine 0.3 gm.	post-arsphenamine	Short
10	44	F	3 injections arsphenamine 0.3 gm.	Erythema	3-4 days
11	28	F	3 injections arsphenamine 0.25 gm.	Erythematopapular	1 wk.
12	20	F	6 injections silver arsphenamine 0.2 gm.	Erythema	3-4 days

CHART III.—NO ARSPHENAMINE DERMATITIS

Cases 13-17			Routine Treatment Cases—No Dermatitis—Strongly Positive Patch Test 5 Positive Out of 135 Tested		
Case	Age	Sex	Arsenical treatment before patch test applied	Patch test	Remarks
13	39	F	14 inj. arsph. 0.3 gm. 2 inj. silver arsph. 0.3 gm.	Strongly positive	No arsenical drugs since.
14	47	F	8 inj. sulpharsph. 0.25 gm.	Strongly positive	No arsenical drugs since.
15	50	F	None	Strongly positive	Given 4 inj. neoarsph. 0.25 gm. No dermatitis.
16	21	F	1 inj. arsph. 0.3 gm.	Strongly positive	Given 6 inj. arsph. 0.3 gm. No dermatitis.
17	42	M	None	Strongly positive	Given 2 inj. neoarsph. 0.1 and 0.3 gm. Mild dermatitis followed second dose.

impurities may occur. Moore, Woo, Gay, and Robinson,² and Schamberg and Wright²¹ cite this possibility. Following out this line of reasoning, we have tried patch-testing some patients who have recovered from an arspenamine dermatitis, with 2 per cent phenol, anilin oil, and a sulphonated oil, with a positive test to sulphonated oil in one instance. Considerably more work must be done on this phase of the subject before any conclusions can be reached.

The second point to consider is the occurrence of positive patch tests in patients with no cutaneous intolerance to the subsequent intravenous administration of the arspenamines. This is more readily explained. A definite threshold amount of antigen seems necessary to produce an allergic response. This amount may vary considerably in individual cases. The amount of neoarsphenamine reaching any given area of cells, when $33\frac{1}{4}$ per cent neoarsphenamine is applied externally for 24 hours, is probably far greater than when the drug is administered by the intravenous route. The occurrence of positive patch tests in the 4 cases out of 135 tested (Chart III) can only be interpreted as an epidermal hypersensitivity, yet the threshold of reaction in these cases is probably too high to be reached by therapeutic doses of the arsenicals administered intravenously.

Charts I and II demonstrate a decided difference in response of patients to further treatment with the arspenamines. As Ffrench,²⁷ Moore and Keidel,⁸ and others have pointed out, there seem to be two main types, the severe vesicular and the mild erythematous or erythematopapular. The severe vesicular form appears to be a definite sensitization to arspenamines or products of their metabolism, but a satisfactory explanation of the milder forms is wanting. They appear wholly unrelated to the severe vesicular types and do not, as shown, contra-indicate further treatment with the arspenamines. Further, they do not appear to represent sensitization phenomena to the arspenamines or the products of their metabolism because subsequent administration of arspenamine is well tolerated. Such cases should be differentiated from the severe forms in which further treatment with the arspenamines is usually unsuccessful. Isolated severe crises have been subsequently treated successfully and Cannon and Kare-

litz¹¹ have had some success with desensitization.

On the basis of the above facts, it is difficult to place any confidence in patch tests as a guide to further arspenamine therapy. The question arises, if skin testing methods are not reliable, how may one differentiate a severe form of sensitization dermatitis in the early stages from one of the benign types? We believe the only satisfactory method is that proposed by Moore and Keidel⁸ who suggested the use of gradually increasing doses of arspenamine or neoarsphenamine starting with 0.01 gm neoarsphenamine or 0.005 gm arspenamine.

Case 1 and Case 17 (Charts I and III) deserve special comment. Case 1, following recovery from the initial attack of arspenamine dermatitis, was given 15 cc of bismocymol intramuscularly. Three days later he developed a generalized dermatitis which lasted about six weeks. Patch tests with the bismocymol were negative. Analysis of the preparation administered revealed only the slightest trace of arsenic. The patient later took 25 injections of bismuth salicylate without further incident. Russell¹⁷ has recently analyzed several bismuth preparations for their arsenic content. He found very slight traces in most of the specimens examined. Cannon and Karelitz,¹¹ and Schoch⁶ report similar cases. The former authors' patient, following recovery from arspenamine dermatitis, proved intolerant to both a mercury and bismuth preparation. Schoch's case developed upon the injection of a bismuth preparation. Schoch believes his case was due to the use of a syringe contaminated with arsenic. We feel that our case was due to neither the use of a contaminated syringe nor to the small amount of arsenic present in most bismuth preparations. This patient was later able to tolerate 0.0004 gm of arspenamine which is considerably more arsenic than Russell found in any preparations that he analyzed. The question arises in this case, whether sensitization to one substance may temporarily produce a polyvalent sensitivity and, for a time, cause a patient to react to other substances of like molecular structure such as the benzene ring.

Case 17 is of interest because the patient had never received any arspenamine preparations prior to the application of the patch test. The patient developed a

epidermal cells. Furthermore, there are numerous reports in the literature incriminating quinine,²¹ codein,²² opium,²³ and other drugs of producing a superficial eczematoid dermatitis from ingestion of the drug in question with subsequent positive patch tests (application of antigen to sensitive cells). Sulzberger and Lewis²⁴ have demonstrated positive patch tests with trichophytin in cases presenting epidermophytids. This is another instance of a blood-born antigen producing an eczematous eruption in which the cutaneous allergy is demonstrable by applications of the antigen from without. Therefore, it is logical to expect a positive patch test where a true cutaneous allergy is present to the arsphenamine molecule. If a positive patch test does not occur, there cannot be

a cutaneous allergy to the arsphenamine molecule. An explanation of this phenomenon may possibly be the phenolic nature of the arsphenamine molecule. The first step in the manufacture of arsphenamine is the fusion of anilin oil with arsenic acid. Cutaneous intolerance is commonly encountered in drugs of the anilin series of which phenols are a part. Kolmer²⁵ states that there are a great number of intermediate compounds formed between arsphenamine, as it is injected, and arsenic as it is stored and eliminated. We know little as to the fate of these organic compounds in the body. Impurities are also present in all arsphenamines such as sulphites, methyl alcohol, ether, etc. It is therefore theoretically possible that sensitivity to any of these split products or

CASE REPORT:

INFLUENZA BACILLUS MENINGITIS WITH RECOVERY

EMANUEL APPELBAUM, M.D.

From the Meningitis Division Bureau of Laboratories, Department of Health, New York City, and from the Fourth Medical Division, Bellevue Hospital

ABSTRACT

The mortality in influenza bacillus meningitis is so high that it is a matter of interest when a patient suffering from it recovers. This case is one of particular interest because the meningitis was complicated by diabetes mellitus and by the development during the course of the disease of pachymeningeal hemorrhage and of spinal subarachnoid block.

J. K., aged 47, admitted to Bellevue Hospital May 8, 1934, in a semi-stuporose state, complained of severe frontal headache and vomiting. The onset of these symptoms was rather sudden, four days prior to admission to the hospital. For the past year he was known to have diabetes mellitus for which he was treated with diet but not with insulin. Eight years ago he sustained a fractured skull.

The physical examination on admission showed a markedly obese patient in a semi-stuporose state from which he could be aroused. The temperature was 101.6°F. and the pulse 102. The respirations were Kussmaul in type. The skin was markedly flushed particularly over the face and neck. There was pronounced nuchal rigidity and generalized hyperreflexia. The Brudzinski sign was positive, but the Kernig negative. There was a positive Oppenheim on the right. There was also a right internal strabismus.

A spinal tap performed on the same day yielded a cloudy fluid under increased pressure. There were 12,380 cells, mostly polymorphonuclears. The albumin and globulin were each, 3 plus, and sugar was absent. Gram negative cocco-bacilli were found on smear but not on culture. After removal of the fluid, 20 c.c. of antimeningococcic serum was injected intraspinally.

As the urine showed 3 plus sugar and a trace of acetone, the patient received shortly after admission 20 units, and an hour later another 10 units of insulin. His urine then showed only a small trace of sugar but no acetone. Thereafter the diabetes was well controlled by employing a relatively high

carbohydrate diet and moderate doses of insulin.

May 9.—The spinal tap yielded 45 c.c. of purulent fluid which showed the gram negative cocco-bacilli on smear but not on culture. 20 c.c. of antimeningococcic serum was given intraspinally. The clinical picture was unchanged. The white blood count was 17,200 with 72 per cent polymorphonuclears and 28 per cent lymphocytes. The blood sugar was 200 and the non-protein nitrogen 30 mgms. per 100 c.c. The Wassermann was negative.

May 10.—The spinal fluid was still purulent, showed 2 plus albumin and globulin and 1 plus sugar. The gram negative cocco-bacilli were not found on smear but were present in the culture. 20 c.c. of antimeningococcic serum was again injected intraspinally. The blood culture was negative.

May 11.—The spinal fluid obtained on this day showed the presence of organisms both on smear and culture. There was however only 1 plus albumin, globulin, and sugar. Antimeningococcic serum was again administered intrathecally.

May 12.—The spinal tap yielded 50 c.c. of cloudy fluid which showed 3 plus albumin and globulin and 1 plus sugar. Both the smear and culture showed the presence of organisms which were definitely identified as influenza bacilli. At this time 20 c.c. of anti-influenza serum was injected intraspinally and 60 c.c. intravenously. Following the intravenous serum administration the patient had a severe reaction, which was promptly relieved by the use of adrenaline hypodermically.

May 13.—The spinal fluid was slightly bloody and xanthochromic, and showed 3 plus albumin and globulin but no sugar. The smear was negative but the culture positive for the influenza bacillus. The patient received 20 c.c. of anti-influenza serum intraspinally and 60 c.c. intravenously.

May 14 and 15.—The spinal fluids obtained on these days were cloudy and xanthochromic,

and showed the presence of organisms on smear and culture. On each of these dates, 20 c.c. of anti-influenzal serum was administered intraspinally and 60 c.c. intravenously. In spite of the active treatment there was no improvement in the patient's condition. The signs of meningeal irritation were pronounced and the temperature ranged between 101° and 104°F. Repeated blood cultures remained negative.

On May 16, the patient developed an extensive serum rash. The spinal fluid remained xanthochromic with 3 plus albumin and globulin and 1 plus sugar, and was positive for the influenza bacillus both by smear and culture. 20 c.c. of anti-influenzal serum was injected intraspinally, but the intravenous use of the serum was discontinued.

From May 17 to 24 inclusive the patient's condition was very bad. He appeared very toxic and at times was irrational. The temperature varied between 101° and 103°. Spinal taps were performed daily, followed by the intraspinal administration of anti-influenzal serum. The fluid in each instance was xanthochromic, contained large amounts of albumin and globulin and a small trace of sugar, and showed the presence of organisms on culture.

On May 25, the temperature dropped to 100°F., but the signs of meningeal irritation with clouding of the sensorium persisted. The spinal tap yielded only 11 c.c. of yellow fluid which showed a large coagulum on standing. On examination the fluid showed 4 plus albumin and globulin, 1 plus sugar and was negative for organisms. No serum was administered.

The spinal fluids obtained on May 26 and 27 remained negative for organisms, but were xanthochromic and coagulated on standing. Anti-influenzal serum was administered after removal of the fluid in each instance. From 3 to 5 c.c. of fresh human complement was added to the serum each time.

On May 28 and 29, only 3 to 4 c.c. of xanthochromic fluid could be obtained by lumbar puncture each time. While the temperature was only 100°F., and the spinal fluids remained sterile, the mental state became distinctly worse. In addition to the semi-stupor there was generalized twitching and irregular breathing of the Biot type. It was now felt that there was a definite spinal subarachnoid block, which raised the intracranial tension. This impression was confirmed by the cisternal tap, which yielded 40 c.c. of xanthochromic fluid under increased pressure. The fluid was negative for organisms. No serum was given this time.

The following day a decided change for the better occurred. The temperature fell to normal. The breathing was regular and the pulse of good quality. Mentally, the patient appeared brighter.

From this time on the patient continued to show progressive improvement. Several more spinal taps were done for relief of pressure. On examination these fluids were still xanthochromic with large amounts of albumin and globulin, and normal sugar, and were negative for organisms. With the exception of moderate neuritic pains in the legs he made a good recovery.

Comment

This case is recited in detail in order to illustrate some interesting and important points. This was by far the most severe form of the disease and yet did not result in death. It is my impression that the use of anti-influenzal serum and repeated spinal drainage were both important factors in this patient's recovery. On the other hand, I do not feel that the addition of small quantities of complement on May 26 and 27 had any bearing on the outcome, as a definite improvement had already occurred in the clinical picture and the spinal fluid was sterile on May 25. The appearance of bloody and xanthochromic fluid on May 13 was probably due to a meningeal or pachymeningeal hemorrhage. Neal, Jackson, and Appelbaum¹ have already called attention to the frequent occurrence of superimposed pachymeningeal hemorrhages in cases of meningitis complicated by constitutional disease, particularly diabetes or syphilis. It seems to me there can be little doubt that a partial spinal block developed later in the course of disease, as indicated by the character of the fluid and the aggravated condition of the patient on May 28 and 29. The striking improvement following the cisternal tap was gratifying.

The various aspects of influenza bacillus meningitis were recently discussed in detail by Neal, Jackson, and Appelbaum.² In that study it was pointed out that this form of meningitis is essentially a disease of young children and that it is caused by strains of influenza bacilli that tend to fall in one group. Particular attention was called to the frequent presence in this disease of bacteremia and toxic degenerative changes in the viscera. With regard to therapy it was stressed that at present there is no adequate method of treatment. However, the early use of the specific serum intravenously as well as intraspinally was advised. It was also suggested that further research should be done toward the development of a more potent serum with high antitoxic as well as anti-bacterial properties.

ON FINDING TUBERCLE BACILLI

J. STANLEY WOOLLEY, M.D.

LOOMIS

With the discovery by Robert Koch in 1882 of the tubercle bacillus as the sole and only cause of tuberculosis, the finding of this bacterium in suspected material became of primary importance and today is a valued function of those clinical laboratories devoted to public health work. The rather crude staining methods of Koch were shortly superseded by the more adequate technic of Ziehl and Neelsen, whose stain is still the method of choice of most laboratories.

The direct examination in which a small piece of suspected material (sputum) is smeared, stained, and examined microscopically is a well-known and useful procedure. This method is still considered adequate by many, but its limitations are obvious. Bacilli are usually not distributed evenly throughout the whole mass of the sputum sample so that this is a sort of "hit or miss" method dependent largely on the skill of the laboratory man in selecting the most likely small portion for examination. Negative results may be obtained when the truth is otherwise.

If one, however, reduces or compresses the insoluble part of the sputum to a small bulk much will be gained and this can be readily achieved by the so-called concentration methods. Briefly these consist in digesting and liquefying *large* amounts of sputum, centrifuging at high speed, and the direct microscopic examination of the sediment obtained or a portion of it. Thus is examined either the whole specimen or a cross section of it, depending on the amount of sediment. For the purpose of digestion the sodium hydroxide method suggested by Petroff¹ yields satisfactory results and is the one used in this report. Sodium hydroxide, in low concentration does not materially affect the staining qualities of the tubercle bacillus, and in most instances the sputum is readily liquefied by it, if kept warm. Shaking hastens the process. The hydroxide is used in 1 per cent or 3 per cent strength in freshly distilled water, combined with equal parts of sputum.

With the weaker dilution one may safely

leave the mixture in the incubator over night; with the stronger usually one-half an hour is adequate. Very gummy sputums may require 2 volumes of hydroxide for digestion. The digested mass is then neutralized with dilute sulfuric acid, centrifuged for 20 minutes or more at good speed, and the sediment examined. The use of dilute acid adds more water, which is a desideratum. The smears obtained will appear quite "dirty" when contrasted with the direct smear, as all insoluble substances in the sputum have been thrown down, mostly ordinary dust, carbon particles, and sometimes food granules.

In the results to be reported the Ziehl-Neelsen stain for tubercle bacilli was used, but modified after the method of Cooper² by the addition of a small amount of salt to warm carbolfuchsin. The salted stain is kept constantly in the incubator for it precipitates on cooling. Staining is done in the usual manner by gentle steaming and the slide is then permitted to cool thoroughly. This is important for the precipitation resulting increases the penetration of the dye and the bacilli seem better stained than when plain carbolfuchsin is used.

For decolorization one has the choice of the usual acid alcohols or dilute sulfuric acid; 15 per cent sulfuric acid and no alcohol was used. Alcohol in itself may decolorize some (young) bacilli, nevertheless hydrochloric acid in alcohol has had wide use. Nitric acid, when old, may be partly changed to nitrous acid which decolorizes even tubercle bacilli. Smears decolorized with sulfuric acid are not as clean as when acid-alcohol is used.

Even with concentration there may be bacilli present which we do not detect, for at least 5,000 bacilli per cubic centimeter of material must be present in any smear before bacilli can be readily seen with the microscope. One observer finds the number as high as 100,000 per cubic centimeter. By mixing carefully counted bacilli in varying amounts with bronchiectatic sputum and making stained smears in the usual way, it was rarely found possible to

demonstrate the bacilli microscopically when less than 5,000 per cubic centimeter were present. (See Table I.)

TABLE I

800,000 per c.c. showed	25 in 50 Fields.
100,000 " " "	5 " "
10,000 " " "	2 " 250 "
1,000 " " "	1 " 500 "
100 " " "	0 " 500 "

This method is not entirely accurate for some of the bacilli may have been washed off in staining, but it clearly and conservatively demonstrates the limitations of the smear examination. Conversely, from 1 to 5,000 bacilli may be present in a small amount (1 c.c.) of sputum sediment and yet the microscope ordinarily fails to reveal them. A negative sputum report may be entirely contrary to the real fact of the case, a matter of vast importance where a diagnosis or a confirmatory diagnosis depends on the laboratory. Recognizing this inadequacy the problem is how to increase the number of bacilli so they will come within the range of vision or give other evidences of their presence. This may be achieved by inoculating the sediment into the guinea pig, by culturing the sediment on media suitable for the growing of rare bacilli, or by doing both when there is sufficient material.

The guinea pig is for all practical purposes a vital culture, self-heating, and of an assured composition, but it has to be fed and is subject to the usual vicissitudes of laboratory animals. Nevertheless, it has long been successfully used for detecting the presence of tubercle bacilli and it is only recently that its preëminence has been questioned. For inoculation, the sputum has to be concentrated as for microscopic examination.

To avoid injuring the bacilli by too long an exposure to sodium hydroxide, the sputum is treated with the 3 per cent strength for not over 30 minutes. After neutralization and centrifuging, the sediment is diluted and inoculated in the groin of a guinea pig. Besides liquefying the sputum the hydroxide destroys or renders inert most of the contaminating bacteria present so that the animal only rarely succumbs to any of these organisms, and is killed when the intradermic tuberculin test (10 per cent O. T.) becomes definitely positive or at the end of three months. The presence of the characteristic lesions

of the disease and the finding of tubercle bacilli in crush smears from these lesions makes the presence of tuberculosis unquestionable. The continued absence of tuberculin sensitiveness (unless the pig is moribund) unfailingly denies the presence of tuberculosis.

A recent examination of our records shows that nearly 50 per cent of the patients coming to the Loomis Sanatorium with a microscopically negative sputum are thrown into the positive group by the method of inoculation. This speaks well for the diagnostic acumen of the examining physician and for the exquisite sensitiveness of the guinea pig.

Formerly it was taught that tubercle bacilli were hard to grow from contaminated material such as sputum, but with newer methods of preparation of material and improved media such isolation is now relatively easy. The sputum may be treated with 3 per cent sodium hydroxide exactly as for concentration, or when very badly contaminated, with dilute sulfuric acid as recommended by Corper.³

Sterile glassware should be used throughout and centrifuge tubes covered with sterile rubber caps. The usual aseptic technic for culturing should be carefully observed. Adequate centrifuging packs the sediment and facilitates its culturing. Egg or potato, with glycerin, have long been used for growing tubercle bacilli. The medium used in this report was a combination of these materials and was made exactly as previously described⁴ except that malachite green was added to make a final concentration of 1 to 2,000 instead of crystal-violet. The potato-egg medium is not difficult to make, keeps well, and is remarkably sensitive. Rare bacilli will grow as well on this medium as on the more complex media of Löwenstein⁵ and Petragnani⁶ with which it has been compared. It is definitely superior to the potato-cylinder medium.⁷

In an experiment in which 47 sputum sediments were tested both by culture on this medium and with animal inoculation, the culture tubes gave 4 positives when the animals were negative (see Table II) and

TABLE II.—CULTURE VS. INOCULATION

Number of sputums	Positive on culture	Positive on G. pig	Pos. on G. pig only	Pos. on culture only	Total positives
47	24	20	0	4	50%

in each instance the bacilli obtained proved to be virulent. Either 20 tubes were seeded with two loopfuls or 10 tubes with 4 loopfuls of sediment for each specimen. The results are all the more remarkable when one realizes that the guinea pig received the balance of the sediment which, in most instances, was many times greater than the amount cultured. The apparent superiority of the culture tube may lie in the fact that the natural forces of resistance of the animal are capable of destroying some of the bacilli whereas such forces are not operative in the test tube. Until sputum culture becomes more universal, either method should be considered adequate.

Guinea pig inoculation is easier than culturing, for it requires less skill and less careful preparation of material. Another advantage is that the animal can receive much more material than is usually convenient to culture and this assures a heavier seeding in the guinea pig than is possible in the culture tube. Materials contaminated with yeast and fungi had better be given animal inoculation as the ordinary alkaline or acid treatment will not destroy these organisms. The disadvantages of the animal are the cost, which includes care, housing, and feeding, the possibility of intercurrent disease, and the fact that guinea pigs do not usually show positive signs of tuberculosis before one month after inoculation.

The culture method requires the service of a skilled technician, one capable of marking and using the medium. The cost of material is negligible and the medium keeps well. One great advantage of the culture method is that positive results can be read much sooner than when inoculation is done. The earliest positive sputum culture was obtained (visible growth) in 8 days. The average time is 18 days. The longest time before a growth occurred was 56 days. The greatest drawback to culturing is the occurrence of contamination. This is not remarkable when one considers what almost putrid material has at times to be utilized. Thoroughness in the preparation of material and proper sealing of the culture tubes will largely eliminate this difficulty and the culture tube should give results equal in every respect to animal inoculation.

The methods outlined above can be utilized in the examination of many other materials for tubercle bacilli. Purulent dis-

charges from the ear, nodes, fistula, and so on, readily lend themselves to digestion and concentration. Pleural fluid, being already liquid only needs prolonged centrifuging before examining. If the fluid is contaminated with other bacteria, the sediment is treated with sodium hydroxide or sulfuric acid before culturing or inoculation. Urine is allowed to settle and the sediment further concentrated by centrifuging. Urine sediment must be treated before inoculation or culture as it is rarely free from contamination. With pleural fluids, prolonged centrifuging is often the key to success. Primary fluids should have sodium citrate added to prevent clotting. The large electric centrifuge is only second to the microscope as an aid to diagnosis, it is a laboratory necessity.

Thus a "certified" diagnosis as regards the presence or absence of tubercle bacilli in any specimen is arrived at. The results represent the best efforts using generally accepted methods. Failures are more apt to be due to improperly obtained specimens than to an actual missing of the bacilli. Repeated examinations may have to be made.

Methods

For sputum examination the Loonius Sanatorium practice is as follows with new patients: (1) Four ounce wide mouth bottle (sterile and new) issued. (2) This must be kept until one ounce of sputum is obtained even if this takes three or four days (which is sometimes not possible). (3) A likely portion of sputum must be examined by direct method on new slide. (4) Concentration (if negative). With 3 per cent sodium hydroxide for one half an hour in incubator, neutralization, centrifuging, and staining. This should be done aseptically if future culturing is anticipated. (5) Inoculation or culture of sediment if still negative.

(Where inoculation or culture is not feasible sputum may be concentrated as follows. To one volume of sputum add an equal part of a digesting fluid consisting of 15 gms. of sodium hydroxide and 10 c.c. of trikresol dissolved in 1000 c.c. of freshly distilled water. Shake well and incubate over night. Then add one volume [half of the sputum plus hydroxide] of 0.4 per cent sulfuric acid mix and centrifuge. Stain sediment for tubercle bacilli. The addition of trikresol to the digesting fluid renders the treated sputum non-infectious. This digesting fluid is in effect a 1 per cent sodium hydroxide solution as a part of the hydroxide combines with the cresols.)

Results

Five hundred samples of sputum received consecutively from patients on their admission to the Loomis Sanatorium and examined according to the methods described above are reported on. (See Table III.) Three hundred and sixteen were

TABLE III.—EXAMINATION OF ADMISSION SPUTUMS

Positive smear	Negative smear		Total
316	184		500
↑ 63% 13% →	Pos. Conc. 66	Neg. Conc. 118	
		Pos. Inoc. or culture 55	
11% → 87%	Total Positives →		437

found positive on direct smear (one slide only). When the negative-smear sputums were concentrated, one-third of them (66) were found positive microscopically and of the remainder, 55 turned out to be positive by inoculation or culture; 437 positives out of 500 sputums resulted in all. A diagnosis of tuberculosis was made in approximately 90 per cent of these cases from *only one specimen of sputum*. The vast majority of these patients had recognized tuberculosis. A few were sent for diagnosis and included cases of bronchiectasis,

lung abscess, and other non-tuberculous pulmonary diseases. These amounted to 4 per cent of the total. In some instances the sputum specimens did not equal the required amount, but all were included.

Comment

It is recognized that the making of several direct smears from various portions of any specimen will tend to increase the number of positives. In fact very small sputum specimens may often be adequately examined by direct smear as practically all of the sputum comes under observation by this method. But with larger amounts it is best not to spend too much time on direct examination but to turn to concentration without delay. If tubercle bacilli are microscopically present concentration will show them. The purpose is to find the bacilli as easily and readily as possible. The only excuse for not concentrating sputum is lack of adequate apparatus.

The additional positives obtained by inoculation or culture are sufficient in number to encourage those laboratories engaged in sputum examination to apply the more refined methods of diagnosis. *No sputum can be said to be truly negative unless it has successfully run the gauntlet of microscope and culture or animal.*

"I WAS SICK, AND YE VISITED ME"

In New York City alone, approximately 700 visits are made daily to the homes of sick home-relief families by physicians supplied by the Medical and Nursing Service of the Emergency Relief Bureau, according to a report from the State Health Department. This service is part of a statewide program initiated in accordance with the rules and regulations for medical and nursing care adopted by the State Temporary Emergency Relief Administration.

Two years ago when the service was started in New York City, about ten to twenty calls were received daily. In the single month of November, 1934, a total of 17,000 calls were answered.

Describing the way in which free medical care is brought to the homes of the needy

in the city, William G. Terwilliger, M.D., director of the Service, in a recent radio talk said that this care is being rendered at about one-fourth of what it would cost for hospitalization of these patients. Every effort is made to maintain the relationship between family and patient. So far as possible, the regular family physician is sent. At present, 3,000 accredited practicing physicians are enrolled with the Emergency Relief Bureau for the care of home relief families. These physicians are not themselves on relief rolls or employed by the Bureau.

A fee of \$2 for each visit to a home-relief family is paid from emergency relief funds supplied by the federal, state and city governments. Only 25 per cent of the cost is carried by New York City taxpayers.

Emulating Error

Social insurance, and particularly sickness insurance, have two main groups of advocates—politicians who seek to placate or win over the masses and friends of labor who desire to improve its condition. Gustav Hartz, famous German economist, comes within both these classifications. A son of the working classes, he has devoted his life to the advancement of trade unionism. His successful career took him as far as the Reichstag, until unions were abolished by Hitler. When a man of this type examines social insurance and rejects it after a half century of operation, it is because it has failed to fulfill its promise to the worker and the state.

Like most observers, Hartz attributes the development of social insurance to widespread poverty. He does not stop here. From his extensive experience he concludes that "social insurance is not only caused by lack of means" but aggravates it and makes it permanent. The worker, who must contribute a relatively large portion of his small earnings, is rarely able to save and is thus forced into a position of perpetual proletarianism.

If the protection afforded were genuine and substantial, there might be an excuse for this form of benevolent despotism. Unfortunately, this has never been the case. The inability to work out an accurate

actuarial estimate of sickness and unemployment risks makes it difficult, if not impossible, to create adequate financial reserves. At best the benefits provided are "too little to live on and too much for starving." In periods of economic crisis the system is threatened with collapse because of an increased demand for help concomitant with diminishing premiums.

The results of fifty years of sickness insurance in Germany are cited by Hartz as a striking example of the weaknesses of this method. The will to get well has been weakened and malingering is common, with the result that the number of sick days lost from work has multiplied five times, even though health in general has improved all over the civilized world. The excessive demands for service by neurotic and dishonest workers frequently overshadow the needs of the genuinely ill.

It is not to be wondered at if the level of medical care is low. The amounts paid for single services or single patients are so small that the physician is driven to mass practice and forced to subordinate quality to volume. The popular demand for expensive medicines has brought about a strict restriction of the use of drugs; doctors may not prescribe what they think best but what the medical regulations permit.

An extensive supervisory system has completely destroyed the confidential relationship between practitioner and patient. Wedged between the demands of the insured for service and the insistence of the insurers upon economy, the medical man is an object of distrust to both factions.

Hartz does not attack social insurance without proposing a substitute. The system of compulsory savings which he advocates conforms to the views of those who believe that people should meet at least part of the costs of any untoward happening from their own pockets at the time of the emergency. It destroys the incentive to malingering, does not require an expensive administrative bureaucracy, and leaves the worker the possibility of accumulating a small capital for the betterment of his economic status.

While there are undoubtedly valid objections to this proposal, its deficiencies are not nearly as serious nor its potential flaws as costly as those of compulsory insurance. Obligatory savings could easily be combined with the principles of universal medical care favored by the profession. Before the Legislature votes on Senator Byrne's proposal to saddle the people with the incubus of compulsory health insurance—a burden that is more easily assumed than cast off—it should study Hartz's comprehensive analysis of the situation in Germany and consider whether precipitate action is necessary or justifiable.

Fair Claims

Statutory protection of the doctor's right to payment is so nebulous that it has long been taken for granted that the physician need not be paid till very late—if ever. Laborers have a recognized lien upon the structures they erect. Lawyers are frequently in a position to deduct their fees from monies collected. Several acts now pending in the State Legislature would enable physicians to collect their bills in certain circumstances where funds are known to be available.

In many accidents the victims receive substantial awards which are granted, in part, to defray the expenses incurred for

medical care. Frequently the doctors who handle such cases—at the scene of the accident, in hospitals, emergency wards, and their own offices—receive not one penny for their services. The measures sponsored by Senator Byrne and Assemblyman Doyle give them a lien upon any damages awarded.

In death the situation is similar. The undertaker is paid out of the first sums realized on the estate. The physician must depend on the good will of the executors or resort to litigation. The Gamble Act gives the bills of hospitals, doctors, and nurses for services during the deceased's last illness parity with the undertaker's charge.

The legislation cited is fair and reasonable. It does not bestow unique privileges upon the medical profession but abolishes discrimination against it in the matter of securing compensation. The rights of the patient are not prejudiced in any way—but neither is it permitted to impose on the doctor's traditional response to an emergency.

For several years these lien bills have been proposed at Albany, only to fall into the limbo of unreported measures. The current Legislature will probably view the interests of the profession with similar apathy unless physicians and their friends bring the pressure of articulate opinion to bear on it.

Prenatal Medication as a Cause of Deafness

It is difficult to attribute the noticeable increase in the incidence of deafness among school children to any one cause. It is likewise hard to determine whether or not this increase is an actual one or has simply become apparent as the result of our more thorough examination of these children, undertaken in the main, with the view of instituting re-educational measures as early as permissible. The fact remains, however, that otologists are seeing more children in the first decade of life whose hearing has been found impaired in the course of the routine examination by the school physician.

The types of deafness encountered

among these patients show an imposing percentage of nerve deafness. This factor has led Taylor¹ to investigate the possible effect of drugs taken by the pregnant mother upon the hearing acuity of her offspring. It is well known that certain drugs have a predilection for the auditory nerve. Quinine, salicylates, and alcohol can affect the eighth nerve permanently. Since the placenta is permeable to drugs, Taylor feels that medicaments, particularly quinine given to induce labor, may have a definite toxic effect upon the acoustic nerve. Dilling and Gemmell² recovered quinine in the urine of newborn babies whose mothers had been given quinine, this finding in the child was evident as long as twelve hours after the last dose had been taken. King³ was able to recover an appreciable quantity of quinine from the brain of a fetus, whose mother had taken the drug.

It is significant that a census of the schools for the deaf in Florida and Alabama showed that the greatest number of children were born in the period of the year when malaria is most prevalent, and when the use of quinine is greatest. This relationship between deafness and the date of birth was not evident in the census of northern schools for the deaf.⁴

This is a new phase in preventive medicine which deserves the attention of the obstetrician, otologist, biochemist, and pathologist for further study. While cases of progressive deafness, deafmutism and otosclerosis will still be with us, a detailed study of the problem presented by Taylor may go far toward eliminating the cases of poor hearing brought about by the administration of drugs prenatally. Here at last is a ray of light upon one of the darker sides of medicine.

Hormonal Treatment of Prostate Hypertrophy

Tent, the Brussels urologist, lately described certain surgeons as "being more enthusiastic about recommending prostatectomy to others than about undergoing it themselves." Nonoperative treatment is certainly of paramount importance in certain cases. It has long been known that some connection exists between the prostate and testicular function. The prostate atrophies after castration and the restoration of the epithelium of this gland which has previously been damaged by castration in rats has been used for the determination of the potency of male sex hormone. The castration treatment of prostatic hypertrophy is based on similar reasoning. In striking contrast, however, is the fact that pathological enlargement of the prostate is observed at just that age at which we have sufficient grounds for assuming a lowered testicular function. However, it is known that the interpretation as pure hypertrophy is no longer tenable.

Aschoff's textbook of pathology maintains that the true senile prostate is atrophic, and that compensatory hypertrophy follows. On embryological reasoning, it has been shown that this hypertrophy may be regarded as a development toward the female type, exactly in analogy with the postmenstrual masculinization frequently noted in women. Recent experiments have shown that marked changes can be effected in the prostate gland by injection of female sex hormone. Injections of large amounts of crystalline follicular hormone bring about metaplasia of the epithelium of certain parts of the gland, and so an enormous increase in the prostate gland that micturition becomes impossible and the animals die of ascending renal infection. On this reasoning E. Laquer and van Cappellan⁵ in Holland have introduced the treatment of prostatic hypertrophy by the injection of male sex hormone. This is still in the experimental stage, but the successes reported would seem to point to the possibility of very interesting findings in the near future.

That Problem of the Common Cold

Herkimer, N. Y.

To the Editor:

The common cold deserves all the attention it has been receiving. If the opinion that I have been expressing is correct, science has been using wondrous methods in studying this disease.

In face of the fact that colds, as the experience of everybody attests, are often caught suddenly and in face of the fact that all known infections have a considerable period of incubation it has been tenaciously held that the common cold is caused by germs and is infectious. There is no good reason for saying that the common cold is the only infection that does not have a period of incubation. Is it not safe to say that if the common cold does not have a recognized period of incubation it is not an infection?

When a person is exposed to chilling and is on the point of catching cold he can prevent catching cold by warming his body so that it is normally warm but I do not know of any infection that can be cut short in its development by that method.

The common cold is a distinct entity but there are infections that resemble it. The fact that common colds are prevalent in a household or community does not in the least prove that they are caused by germs and are infectious, for necessarily colds are most prevalent when atmospheric conditions favor their development. At such times people gather indoors and these are the conditions under which infections spread. These mimicking infections and common colds are naturally prevalent at the same time. Furthermore, mucous membranes that are irritated by common colds often become infected by these mimicking infections. These facts cause much of the confusion and difficulty in differentiation and experimentation. Cultures of unknown nature have been used for experimenting and uncertain results have been declared as certain.

The problem of the nature of the common cold has been grossly and ridiculously complicated by including in its category, as forms of colds, diseases that are known to be distinct entities. A recent article in the JOURNAL stated: "For purposes of classification the colds were divided into acute coryza, sub-acute colds, influenza, pharyngitis, and other respiratory infections"!

As for the prevention of colds, it appears that each individual, besides maintaining the best possible general health, should learn the customary limits of exposure beyond which he is apt to catch cold and should try to stay within those limits. Sufficient clothing in cold weather and the avoidance of becoming chilled, especially when sweaty, are the chief preventives.

Editor,
N. Y. State Journal of Medicine
33 West 42nd Street
New York City

Dear Sir:

My attention has been called to a statement in your issue of February 1 in the section devoted to "Current Comments," to the effect that I was one of the persons who assisted in drafting the health insurance bill of the American Association for Social Security. This is an entirely false statement. I had nothing to do with the drafting of this bill and was not consulted in any manner; in fact, I did not know that such a bill was being prepared until I received a copy thereof.

As your statement put me and this Committee in an entirely false light before your readers, I shall expect you to make prompt correction. Will you kindly send me a copy of such correction?

Very truly yours,
COMMITTEE ON ECONOMIC SECURITY

EDWIN E. WITTE,
Executive Director

[We are glad to have this information and make this correction.—Ed.]

Presidential Message

February 19, 1935

To the House of Delegates and Members of the Medical Society of the State of New York: Greetings!

At a special meeting of the House of Delegates of the American Medical Association held in Chicago on February 15 and 16, 1935, resolutions of great importance were adopted. I ask your serious attention to the report of the Committee which is herewith appended.

It is with great pleasure that I inform you that our delegation took an active part in the proceedings and that our own Nathan Van Etten, the Vice-Speaker of the House, was on the Committee which drew up the general resolutions. During the four sessions every delegate had a chance to express his personal opinion as well as to report the action of his State Society on the important questions involved in the various bills presented to them for critical analysis. It is with the greatest pride in the medical profession of this country that I announce that all decisions were unanimous.

Once again the only association which truly represents organized medicine in the United States, the American Medical Association, has restated its opposition to all forms of compulsory sickness insurance, that there is no real demand for a change in the method of delivery of medical service which has stood the test of time, and that there is every reason to condemn the socialistic schemes which in other countries have proved to be extravagant in cost and unsatisfactory in results.

As President of the State Society I ask each and every one of you to inform your patients of this action and make it clear to all with whom you come in contact that organized medicine stands for the protection of the home in all that pertains to the realm of health, including the prevention and cure of disease.

ARTHUR J. BEDELL, *President*

Report of the Reference Committee—Special Session House of Delegates

February 15 and 16, 1935

Your Reference Committee, believing that regimentation of the medical profession and lay control of medical practice will be fatal to medical progress and inevitably lower the quality of medical service now available to the American people, condemns unreservedly all propaganda, legislation or political manipulation leading to these ends.

Your Reference Committee has given careful consideration to the record by the Board of Trustees of the previous actions of this House of Delegates concerning sickness insurance and organized medical care and to the account of the measures taken by the Board of Trustees and the officials of the Association to present this point of view to the government and to the people.

The American Medical Association, embracing in its membership some 100,000 of the physicians of the United States, is by far the largest medical organization in this country. The House of Delegates would point out that the American Medical Association is the only medical organization open to all reputable physicians and established on truly democratic principles, and that this House of Delegates, as constituted, is the only

body truly representative of the medical profession.

The House of Delegates commends the Board of Trustees and the officers of the Association for their efforts in presenting correctly, maintaining and promoting the policies and principles, heretofore established by this body.

The primary considerations of the physicians constituting the American Medical Association are the welfare of the people, the preservation of their health and their care in sickness, the advancement of medical science, the improvement of medical care, and the provision of adequate medical service to all the people. These physicians constitute the only body in the United States qualified by experience and training to guide and suitably control plans for the provision of medical care. The fact that the quality of medical service to the people of the United States today is better than that of any other country in the world is evidence of the extent to which the American medical profession has fulfilled its obligations.

The House of Delegates of the American Medical Association reaffirms its opposition to

all forms of compulsory sickness insurance whether administered by the Federal government, the governments of the individual States or by any individual industry, community, or similar body. It reaffirms, also, its encouragement to local medical organizations to establish plans for the provision of adequate medical service for all of the people, adjusted to present economic conditions, by voluntary budgeting to meet the costs of illness.

The medical profession has given of its utmost to the American people, not only in this but in every previous emergency. It has never required compulsion but has always volunteered its services in anticipation of their need.

The Committee on Economic Security, appointed by the President of the United States, presented in a preliminary report to Congress on January 17 eleven principles which that Committee considered fundamental to a proposed plan of compulsory health insurance. The House of Delegates is glad to recognize that some of the fundamental considerations for an adequate, reliable, and safe medical service established by the medical profession through years of experience in medical practice are found by the Committee to be essential to its own plans.

However, so many inconsistencies and incompatibilities are apparent in the report of the President's Committee on Economic Security thus far presented that many more facts and details are necessary for a proper consideration.

The House of Delegates recognizes the necessity under conditions of emergency for federal aid in meeting basic needs of the indigent; it deprecates, however, any provision whereby federal subsidies for medical services are administered and controlled by a lay bureau. While the desirability of adequate medical service for crippled children and for the preservation of child and maternal health is beyond question, the House of Delegates deplores and protests those sections of the Wagner bill which place in the Children's Bureau of the Department of Labor the responsibility for the administration of funds for these purposes.

The House of Delegates condemns as pernicious that section of the Wagner bill which creates a social insurance board without specification of the character of its personnel to administer functions essentially medical in character and demanding technical knowledge not available to those without medical training.

The so-called Epstein bill, proposed by the American Association for Social Security, now being promoted with propaganda in the individual States, is a vicious, deceptive, dangerous, and demoralizing measure. An

analysis of this proposed law has been published by the American Medical Association. It introduces such hazardous principles as multiple taxation, inordinate costs, extravagant administration, and an inevitable trend toward social and financial bankruptcy.

The committee has studied this whole matter from a broad standpoint, considering many plans submitted by the Bureau of Medical Economics as well as those conveyed in resolutions from the floor of the House of Delegates. It reiterates the fact that there is no model plan which is a cure-all for the social ills any more than there is a panacea for the physical ills that affect mankind. There are now more than 150 plans for medical service undergoing study and trial in various communities in the United States. Your Bureau of Medical Economics has studied these plans and is now ready and willing to advise medical societies in the creation and operation of such plans. The plans developed by the Bureau of Medical Economics will serve the people of the community in the prevention of disease, the maintenance of health, and with curative care in illness. They must at the same time meet apparent economic factors and protect the public welfare by safeguarding to the medical profession the functions of control of medical standards and the continued advancement of medical educational requirements. They must not destroy that initiative which is vital to the highest type of medical service.

In the establishment of all such plans, county medical societies must be guided by the ten fundamental principles adopted by this House of Delegates at the annual session in June, 1934. The House of Delegates would again emphasize particularly the necessity for separate provision for hospital facilities and the physician's services. Payment for medical service, whether by prepayment plans, installment purchase, or so-called voluntary hospital insurance plans, must hold, as absolutely distinct, remuneration for hospital care on the one hand and the individual, personal, scientific ministrations of the physician on the other.

Your Reference Committee suggests that the Board of Trustees request the Bureau of Medical Economics to study further the plans now existing and such as may develop, with special reference to the way in which they meet the needs of their communities, to the costs of operation, to the quality of service rendered, the effects of such service on the medical profession, the applicability to rural, village, urban, and industrial population, and to develop for presentation at the meeting of the American Medical Association in June model skeleton plans adapted to the needs of populations of various types.

HARRY H. WILSON, M.D., *Chairman*

Society Activities

Committee on Legislation

BULLETIN NO. 6, FEBRUARY 13, 1935

Have you written to your legislators asking them to support the following bills and given them a reason for doing so? If not, do so at once, because they are waiting to hear from you; and have some of your friends outside the profession write them also:

Senate Int. 19; Print 774, N. A. O'Brien, and Assembly Int. 19; Print 957, Kantowski—Medical Abuses Bill.

Senate Int. 208; Print 211, Byrne, Lien Bill. Assembly Int. 461; Print 471, Stewart, Clinical Laboratory Bill.

Assembly Int. 372; Print 380, Doyle, Public Health Council.

Assembly Int. 371; Print 817, Doyle, Physicians' Lien Bill.

The opposition to our Physicians' Lien Bill is extremely powerful. It includes the Bar Association and certain large employers of labor, as the New York Central Railroad Company, and the like. Every letter counts, so write today.

New Bills. Since the issuance of our last bulletin the following bills have been introduced:

Senate Int. 693, Twomey, amending the Mental Hygiene Law by providing no member of board of visitors of any institution in Department shall have financial interest, directly or indirectly, in purchase or use of medicines nor in care and treatment of patients. Referred to the Health Committee. Same as Assembly Int. 978, Alterman.

Senate Int. 706, Wicks, amends Chapter 798, Laws of 1931, relative to Temporary Emergency Relief Administration, by extending emergency period to February 15, 1936, and providing for an additional member of administrative authority who shall be member of State Board of Social Welfare. Same as Assembly Int. 906, Killgrew.

Senate Int. 707, Byrne, adds new section to General Municipal Law for hospitalization of members of city fire departments, cost thereof to be city charge. Referred to the Cities Committee. Same as Assembly Int. 887, Hayes.

Senate Int. 754, Williamson, amends the Surrogate's Court Act, for payment by an executor or administrator, out of first moneys received, of reasonable hospital, physicians, surgeons, and nurses bills. Referred to the Judiciary Committee.

Senate Int. 755, Byrne, amends Chapter 802, Laws of 1934, relative to licensing private or public institutions for care of children, and so on, by providing act other

than sections 3, 4, and 5 shall take effect October 1, 1936. Referred to the Codes Committee.

Senate Int. 787, Byrne, amends the General Corporation Law for acquisition of property by a foreign corporation organized not for profit but exclusively for educational, religious, benevolent, or other like purposes, free of five-year tenure restriction, and making other changes relative to acquisition of property by any foreign corporation. Referred to the Judiciary Committee. Same as Assembly Int. 1063, Moffat.

Senate Int. 792, Feld, amends Chapter 798, Laws of 1931, by defining "home relief" to include shoes, books, carfare, eyeglasses, and other necessities, clothing to be "suitable." Referred to the Relief and Welfare Committee. Same as Senate Int. 577, Feld; Assembly Int. 800, McGrath.

Senate Int. 794, Feld, amends the Education Law and Public Welfare Law by requiring public welfare officials to furnish indigent children with carfares and eyeglasses, and appropriating \$1,000,000. Referred to the Relief and Welfare Committee.

Senate Int. 802, Mandelbaum, amends the Education Law for licensing school psychiatrists, psychologists, medical inspectors, aurists, school psychiatric social workers, and certain other employees of boards of education, and validating certain examinations held and licenses issued. Referred to the Education Committee.

Senate Int. 807, Twomey, amends the Education Law by making unprofessional conduct or fraud and deceit in practice of his profession, grounds for revoking license to practice pharmacy, and prescribing procedure for revoking licenses and registration certificates. Referred to the Education Committee.

Senate Int. 825, Coughlin, adds new section to the Public Health Law, requiring health commissioner to make rules for cleansing and disinfecting public telephone instruments, defacing or depositing in a booth refuse or waste material being unlawful. Referred to the Health Committee. Same as Assembly Int. 1025, Doyle.

Senate Int. 862, Graves, adds new section to the Public Welfare Law for removing a person within a county public welfare district to town or city of his settlement therein. Referred to the Relief and Welfare Committee. Same as Assembly Int. 1024, Daniels.

Senate Int. 869, Fearon, amends the Decedent Estate Law by providing in every action for wrongful act or neglect now or hereafter pending in addition to any other lawful element of damages recoverable, reasonable expenses of medical aid, nursing, and attention incident to injury causing death

and reasonable funeral expenses, shall be deemed proper elements of damage. Referred to the Judiciary Committee. Same as Assembly Int. 1193, Parsons.

We should all approve of this bill and let us do so by writing to our Senators and Assemblymen telling them about it.

Senate Int. 898, Warner, amends the Education Law for medical treatment of pupils within a school hygiene district afflicted with defective sight or hearing or other physical disability, medical inspector having been notified that parents are unable to provide necessary relief. Referred to the Education Committee. Same as Assembly Int. 1157, Marble.

It is estimated that from 4 per cent to 12 per cent of all school children have defective hearing. They are are not deaf, yet some of them hear so little that unless they are sitting in the fore part of the room they will not hear what is said and frequently are classed as dull or indifferent students, until their disability is discovered. The school medical inspectors are reporting the existence of these children at present, but facilities for their care and treatment are lacking.

Assembly Int. 1009, Potter, adds new section to the Lien Law by providing for liens of hospitals for care of persons injured as a result of negligence of other person or corporation. Referred to the Judiciary Committee.

Assembly Int. 1061, Messer, amends the Public Welfare Law by making State responsible for public care of any person having no settlement in any public welfare district, provision that he must not have resided in any district for 60 days during year prior to application being stricken out, and making other changes. Referred to the Relief and Welfare Committee.

Assembly Int. 1106, DiFede, amends the Education Law relative to misbranding drugs where package fails to bear statement of percentage by volume of poisons listed in schedules A and B, section 1364. Referred to the Education Committee.

Assembly Int. 1151, Haskell, adds new section to the Penal Law, making it unlawful for a milk dealer, storekeeper, or other person to sell milk at price less or more than price fixed by commissioner of agriculture for the particular transaction; also prohibiting devices for evading such fixed price. Referred to the Codes Committee.

Assembly Int. 1152, Haskell, Agriculture and Markets Law, empowering Department to regulate pasteurization and bottling of milk and making it unlawful to pasteurize or bottle milk for consumption in State which the dealer has sold at a price less than the minimum price fixed for such sales. Referred to the Agriculture Committee.

ACTION ON BILLS

Senate Int. 20 (late Print 943), workmen's compensation, disabling disease, has reached third reading.

Senate Int. 619, motor fuel tax, has reached third reading.

Senate Int. 620, motor fuel, additional tax, has reached third reading.

Senate Int. 302, Health Law, grants and gifts to hospitals, and so on, has passed.

Senate Int. 643, State aid to municipalities, has been reported.

Senate Int. 123, workmen's compensation, carrier's physician, has been reported.

Senate Int. 706, extending TERA, has passed.

Assembly Int. 816, motor fuel, additional tax, has reached third reading.

Assembly Int. 818, motor fuel tax, has reached third reading.

Assembly Int. 498, Health Law, grants and gifts to hospitals, and so on, has reached third reading.

Assembly Int. 321, health districts, cities, nurses, has passed.

HEARINGS

Feb. 20—As. Int. 558 { Working hours of nurses in public hospitals; hearing before Assembly Committee on Labor and Industry.

Feb. 26—As. Int. 202 { Civil Service examinations; hearing before Assembly Committee on Judiciary.

Feb. 27—As. Int. 150 { Workmen's Compensation Law, medical care; hearing before Assembly Committee on Labor and Industry.
As. Int. 210

As. Int. 644 { Workmen's Compensation Law, occupational diseases; hearing before Assembly Committee on Labor and Industry.

As. Int. 740 { Workmen's Compensation Law, appearances, attorneys; hearing before Assembly Committee on Labor and Industry.

Committee on Legislation

Current Comment

This is the second time in the history of the American Medical Association that a Special Meeting of its House of Delegates has been made necessary. The first time a national emergency impended—the United States was about to embark upon a great war. The organized profession then assembled its representatives and from the deliberations there ensued a fine medical organization which took its place in the armed forces of the country. The record made by organized medicine during the War is history. Our people were on the whole better served than those of our allies, and the country is proud of the results achieved. Now, too, a national emergency impends. The very life of the profession is at stake and the type of service which it is to render to people of our country is the issue. The high quality of service to all the people of the United States is threatened.

The so called "Epstein bill," proposed by the American Association for Social Security and now being promoted in individual states, is a vicious, deceptive, dangerous, and demoralizing measure. It introduces such hazardous principles as multiple taxation, inordinate costs, extravagant administration and an inevitable trend towards social and financial bankruptcy.

New York Medical Week, date of February 9 says, "The labor leaders who are favoring compulsory health insurance should study the Byrne bill to see who is to receive the money deducted from the pay envelope of the worker. On the Health Insurance Board, in addition to a \$10,000 director, there will be three appointees receiving \$7,500 each, plus traveling expenses. A State general advisory council of twelve and a State medical advisory council of nine will also be entitled to traveling and other incidental expenses. An unsuspected number of districts will each have a full time finance and full time medical supervisor. Each district in turn will be subdivided into local areas, each with an office headed by a full time finance manager and full time medical manager. Local councils of four to seven members will receive per diem fees and traveling and incidental outlays. Unlimited local advisory committees appointed by these local councils will also enjoy the privilege of traveling and incidental expenses. All this, of course, is to lower the costs of medical care!"

Dr. Manfred M. Zachard, a physician who has had a very large experience with sick benefit insurance in Germany, says, "There

were over two hundred sick benefits in Berlin. The fees paid by them to the physicians amounted to about 5 to 6 per cent of their respective expenses." He further states that "for obvious reasons the physician working under the fund often declined to declare the patient as recovered and able to work. Cases then went to a supervising physician and if then the patient and doctor could not agree, the insured could be examined by another supervising physician. Finally, it was still possible to have arbitration." He goes on to say, "The popularity of an insurance physician was not dependent upon his medical ability but the medical men who prescribed the most medicine or other remedies, especially when they did so without lengthy examinations, were most favored. The patient's gradually growing realization of the fact that he had a legal right to sick benefit assistance undoubtedly aroused disproportionate greed on his part. In many cases bureaucratic organization of the sick benefit insurance aroused bitterness in physicians and patients."

The *Bulletin* of the Medical Society of the County of Monroe says, "Any physician who has been privileged to arrive at degrees of stability and skepticism and foresight from his own experience in his life work knows that no system of medical practice can survive which fails to take into account moral wisdom, deep faith, and personal loyalties. He is warranted in the assurance that any failure to cherish and preserve the ideals of present medical practice cannot endure in our civilization."

Dr. George Hoyt Whipple, responding to the testimonial dinner commemorating his winning of the Nobel Prize, said, among other things, "It behooves teachers to encourage serious discussions of these questions coming to conclusions that may be tested. Members of the medical societies should co-operate in conclusions reached by organized medicine."

In his annual address on his inauguration as President of the New York Academy of Medicine, Dr. Eugene H. Pool said that "despite the depression and the fact that those in poverty must be fed, clothed, sheltered, and cared for when ill, the deplorable living wage now given the doctor would only bring about inferior grades of physicians unless this condition be remedied in some manner." He said that in 1934, 9,500,000 patient days care were provided by hospitals of the city (New York) and 6,800,000 patient out days were

afforded, for which members, with few exceptions, received no recompense. Continuing, he said, among other things, "Medical men of a community may agree among themselves as to a basis for charges. They should, as complete groups in various communities, try such methods as offer the greatest promise. Criti-

cal study of experience of this nature should be carried out before the final program is proposed. Any plan should be a corporated community organization so that all unfair competition may be avoided. The choice of physician or surgeon should rest with the patient."

Additional Notes on Income Tax Deductions

Taxes on real estate and personal property paid during the year 1934 are deductible. So-called taxes, which are assessed against local benefits, such as streets, sidewalks, drainage, and other like improvements, are not deductible, for they tend to increase the value of the property and thus constitute cost of a permanent improvement. The Federal income tax may not be deducted. Income tax, however, paid to the State by an individual on his income is an allowable deduction on his Federal income-tax return.

Customs duties paid by a person on articles imported for his own use are deductible. Admission taxes, imposed on admissions in excess of 40 cents, are deductible, but the taxpayer must show that account has been kept of the amount paid. Taxes on club dues are deductible by the member paying them. An individual may deduct the tax on his telephone conversations, radio messages, telegrams and cables, on the checks he has drawn, and on the rent of his safe deposit box.

License fees exacted by a State or city upon certain businesses are deductible as taxes. Automobile license fees are ordinarily taxes and deductible. Postage is not a tax and is not deductible. In general, taxes are deductible only by the person upon whom they are imposed.

Under the Revenue Act of 1934, no Federal estate taxes, State inheritance, estate, legacy, or succession taxes, or gift taxes are deductible on any income-tax return. The Federal taxes on automobiles, gasoline, and liquor are imposed upon the manufacturer, producer, or importer, and are not deductible by the purchaser or consumer. Whether or not the gasoline tax or the sales tax levied by a State may be deducted by the individual purchaser depends upon the terms of the State law imposing the tax, consequently the right to the deduction, as between purchaser and seller, varies in the different States.

If an automobile is used for both business and pleasure, all of the maintenance and operating expenses connected therewith, which constitute allowable deduction for Federal income-tax purposes, should be allocated to the two uses on the basis of the time that it is used for each. For example, if the total expense of operation and maintenance, plus depreciation, for the taxable year amounted to \$800, and the car was used three-fourths

of the time for business and the balance of the time for pleasure, the allowable deduction for Federal income-tax purposes would be \$600.

If a law which imposes a tax on gasoline shows that the tax is imposed on the consumer and not on the dealer, the consumer may deduct as a tax, for Federal income-tax purposes, the amount of the gasoline tax paid by him; but the taxpayer must have kept records of the payment of such taxes in order that the deduction may be substantiated as is required by the law and the regulations. The Federal gasoline tax imposed by section 617 of the Revenue Act of 1932 as amended is not deductible by the consumer. A taxpayer may ascertain whether the gasoline tax imposed by a State is deductible by the consumer or by the dealer by addressing an inquiry to the collector of internal revenue for his district.

In any case where the gasoline purchased is used for business purposes the tax may be added to the cost of the gasoline and deducted as a business expense; but where that is done, the gasoline tax cannot be deducted separately under the item of taxes.

The revenue act provides for "a reasonable allowance for the exhaustion, wear and tear of property used in the trade or business, including a reasonable allowance for obsolescence." For convenience, such allowance usually is referred to as depreciation.

In claiming a deduction for depreciation several fundamental principles must be observed. The deduction must be confined to property actually used in trade, business, profession, and to improvements on real property, other than property used by the taxpayer as his personal residence. In general, it applies to the taxpayer's capital assets—buildings, machinery, and so on—the cost of which cannot be deducted as a business expense.

A lawyer, doctor, or other professional man may not charge off as a current expense the cost of a library used wholly in his profession, this being a capital expenditure and the library a capital asset, but he may deduct an allowance for depreciation based upon the useful life of the library. If part of a professional man's residence is used by him for office purposes, a proportionate amount of the depreciation sustained may be deducted, based

generally on the ratio of the number of rooms used for such purposes to the total number of rooms in the building. The same principle applies if a taxpayer rents to others a portion of his residence. Under such conditions, however, the taxpayer must include in his gross income the rentals received.

The amount to be recovered by depreciation is the cost of the property, if acquired after February 28, 1913. If acquired by purchase prior to that date, the basis is the cost of the property, less depreciation sustained prior to March 1, 1913, or the value on March 1, 1913, whichever is greater.

The proper allowance for depreciation is that amount which should be set aside for the taxable year in accordance with a reasonably consistent plan (not necessarily a uniform rate), whereby the aggregate amount so set aside, plus the salvage value, will at the end of the useful life of the property equal the cost or other basis of the property.

The depreciation rate of a building is not based upon the number of years it will stand before being condemned and razed, but on the number of years it will remain habitable or serviceable for the purpose constructed.

If the taxpayer builds a new building, the period over which depreciation may be claimed begins at the time the building is completed and capable of being used. Buildings under construction are not subject to a depreciation allowance.

If it is clearly shown that, because of economic or other conditions, property must be abandoned at a date prior to the end of its normal useful life, so that depreciation deductions alone are insufficient to return the cost or other basis, a reasonable deduction for obsolescence may be allowed in addition to depreciation. No deduction for obsolescence is permitted because, in the opinion of the taxpayer, the property may become obsolete at some future date.

TWO AMERICAN SOCIAL HYGIENE ASSOCIATION PUBLICATIONS

The American Social Hygiene Association, with offices at 50 West 50th Street, New York City, has recently announced the publication of miniature editions (8½ by 11 inches) of two exhibits. The first of them, *The Treatment of Syphilis*, shown in the American Medical Association's Scientific Exhibit in Cleveland last June, includes 24 charts made from a study of 8,000 cases at Johns Hopkins University, University of Michigan, The Mayo Clinic, University of Pennsylvania, and Western Reserve University in cooperation with the United States Public Health Service. The price is 30 cents a set, \$3.00 a dozen sets, postpaid. Special statements by Doctors Stokes, O'Leary, Wile, Moore, and Cole, regarding the treatment of syphilis, have been prepared to accompany this exhibit. The price for this collection is 10 cents a set, 80 cents a dozen. The charts, by titles, are as follows:

- 1 Mucocutaneous relapse during lapse of treatment, according to stage in which treatment was begun.
- 2 A. Site of mucocutaneous relapse lesions. B Time relation of mucocutaneous relapse
- 3 Comparison of treatment in 204 mucocutaneous relapses
- 4 Relation of arsenamine to the prevention of mucocutaneous relapse.
- 5 The sites of secondary lesions in 2,269 patients
- 6 Incidence of early asymptomatic neurosyphilis
- 7 Incidence of asymptomatic neurosyphilis according to stage of disease in which treatment was begun
- 8 Relation of blood Wassermann fastness to spinal fluid abnormalities in early syphilis
- 9 Positive darkfield examinations by stages of early syphilis
- 10 Treatment methods
- 11 Comparative effectiveness of treatment methods
- 12 Comparison of effectiveness of treatment methods in securing Wassermann reversals in one year.
- 13 Effect of prolonged treatment on satisfactory results
- 14 Percentage of satisfactory and unsatisfactory results obtained with indicated amount of treatment

15 The value of x-ray of the cardiovascular stripe in clinically latent syphilis.

16 The prognostic value of negative spinal fluid in latent syphilis

17 Frequency of symptomless infection

18 Outcome of pregnancy in untreated latent syphilis

19 Effect of treatment of syphilitic pregnant women with negative Wassermanns

20 Effect of treatment of syphilitic pregnant women

21 Results of treatment in latent syphilis, continuous vs. intermittent or irregular treatment

22 Results of treatment in latent syphilis by gross amount of treatment given

23 Results of treatment in latent syphilis according to the total length of observation

24 Influence of Wassermann fastness on the tendency toward clinical relapse

The second exhibit, *Gonorrhea in the Male*, also shown as part of the Scientific Exhibit of the American Medical Association, a few years ago, includes 10 charts, prepared by Dr. Edward L. Keyes, regarding the diagnosis and treatment of acute and chronic gonorrhea. The price is 10 cents a set, 80 cents a dozen. These charts may also be had in the form of thirteen slides, including five drawings in color. The price is \$8.00 per set, or they are available for rental at \$1.00 per day.

The Association believes this material should be useful in a variety of ways. As instruction for medical students it would be advantageous to place a copy of these handy exhibits in the hands of each senior, or at least to display the exhibit for students to examine. The material can also be used in talks to medical societies. The small charts may be set up as an exhibit or lantern slides could be made of each chart. Another use, the Association believes, is for the instruction of such people as nurses and social workers.

County Societies

Albany County

"Three types of nurses" were classified by Dr. Edgar A. Vander Veer as "those who have a love for their profession, those who become nurses for the money they think there is in it, and a few who have hopes of getting a husband." He was one of the speakers at graduation exercises for the 59th class of the National Training School for Certified Nurses in the Albany Institute of History and Art.

"Yours is a noble calling," Dr. Vander Veer declared. "It calls for hard work, for sincerity, and a sympathetic understanding."

He had several "don'ts" to offer to the nurses. Among them were: "Don't try to be the doctor. When you go into a home you will find it disorganized by sickness; don't let your presence disorganize it any further. Don't expect too much waiting on by members of the family, but do what you can to aid them."

Erie County

Dr. Samuel W. Hartwell, newly appointed head of the department of psychiatry at the University of Buffalo, will be director in charge of a new child guidance clinic to open soon at 88 Goodell Street.

Fulton—Montgomery Counties

A new State health district comprising Fulton and Montgomery Counties has been established and began to function on January 1. Like the other fourteen health districts in the State, the new district has been organized under Section 4-A of the Public Health Law which provides for the division of the State into districts, each one administered by a district state health officer appointed by and directly responsible to the State Commissioner of Health.

The primary object of setting up the new district, says the State Health Department, is to determine the relative efficiency of a small well-staffed State health district as compared with a County health department. Such an experiment is necessary because it has been amply demonstrated that New York State communities are loath to abolish local boards of health as required in the formation of County departments of health despite the fact that few places except certain of the large cities have adequate health service under the present type of organization.

The area selected for the new district comprises less than 1,000 square miles and has roughly 106,000 inhabitants, 30 per cent

of whom live in strictly rural territory. As now planned, a full-time district State health officer will be stationed in this area, together with a sanitary engineer and a staff of public health nurses.

Jefferson County

Intimate glimpses into the human side of medical history, gleaned from more than 50 years of practice, were given by Dr. E. A. Simonds, of Carthage, in a Rotary Club talk on January 29. When Dr. Simonds started practicing in Carthage over 50 years ago, he said that the customary fee for office treatment was 50 cents. A confinement case called for a \$5 fee. As public health officer his salary was \$50 per year, with \$3 a day for the work if he devoted his full time to it.

He mentioned the laxity in medical regulation in the years after the Civil War, when a few weeks' course of training and \$25 would give almost anyone a license to practice medicine. In his own case, however, he said that for many years he made it a practice never to have a newspaper, magazine, or novel in the house, and to spend at least an hour of every day in the study of medical subjects in order to keep abreast of the times in theory as well as practice.

Nassau County

Sensational newspaper articles published in Freeport allege that 58 per cent of the nearly \$200,000 paid for medical services by FERA in Nassau County last year went to 38 doctors, while the remaining 343 medical men received only \$70,000. One doctor is said to have had nearly \$14,000 of the medical relief funds, and several around \$8,000 each. The *Nassau Review* says that the County Medical Society is investigating the truth of these reports.

New York County

A Negro newspaper remarks that "a ray of hope for Negro physicians was cast by the promotion of Dr. St. Elmo E. Taylor, of 54 Jefferson Avenue, to the post of assistant visiting dermatologist and syphilologist at Cumberland Hospital, where for the past two years he was clinical assistant. This is the first time in the history of Brooklyn that a Negro physician has been called upon to serve in such a capacity.

"The appointment was made by Commissioner S. S. Goldwater, who is now under fire for refusing to appoint Negro physicians

to the staff of the new Queensboro General Hospital. The fight in this instance is being waged by the Committee for Equal Opportunities, the members of which consists of both colored and white professional and business people."

Five hundred physicians and nurses of the New York Post-Graduate Medical School and Hospital of Columbia University paid tribute to the surgical skill and leadership of Dr. John Frederick Erdmann, former director of surgery at the Hospital, at a dinner at the Biltmore on January 26.

Dr. Erdmann resigned from the hospital last summer to devote himself to his private practice which has become one of the most extensive in New York since he entered abdominal surgery 48 years ago. Joining in the tribute were Dr. Charles Gordon Heyd, his successor; Dr. Allen O. Whipple, professor of surgery at the College of Physicians and Surgeons, Columbia University, and Dr. John J. Moorhead, a member of the Hospital staff.

Onondaga County

Syracuse lost a brilliant physician on January 30, when Dr. J. Raymond Burns, former chief of staff of three of Syracuse's largest hospitals, died at his home, after a lingering illness. He was 46. He received his degree before he was 21, and had to serve as an interne for years in various hospitals before he was old enough to begin practice. He established the first prenatal clinic in Syracuse and for a number of years was Associate Professor of Obstetrics at Syracuse University.

Queens County

Dr. Carl Boettiger, of Flushing, a former president of Queens County Medical Society, has been appointed temporary chairman of the newly organized medical board of the new Queens County General Hospital. Dr. Frank Dealy of Flushing has been appointed temporary secretary. The hospital will open about July 1.

While condemning social medicine, Dr. Morris S. Bender declared in his presidential address to the Queens County Medical Society that doctors must re-establish their profession so that "every human being can obtain the most modern treatment regardless of his earning capacity. The American people are patiently awaiting the profession's action. Medical practice will have to be regulated as any other business to accomplish this goal.

"Health service in many instances has become almost a luxury. We have permitted

institutions, the workshops of physicians, to operate like vast hotels. But modern scientific medicine is worthless unless it can reach every human being, regardless of economic status.

"The physician must recognize that the mental attitude of the people is changing and everyone is looking into the future with hope. The old order of things is gone, never to return, and with vision we shall move forward to a higher order of social prestige through which all mankind will be benefited."

Warren County

The Glens Falls Academy of Medicine at a meeting on January 24 renewed its fight for a Glens Falls Medical Center, and a committee was appointed by Dr. Conrad R. Hoffman, chairman of the meeting, to confer with groups from the Glens Falls Hospital Board and the local Chamber of Commerce on the erection of the institution.

Despite their setback in the first effort to have the erection of a medical center endorsed by the people of the city, they will continue to push the plan until such endorsement is obtained, members of the Academy announced.

Westchester County

Many will remember the report made some time ago by the Westchester Committee on Economics on the cash value of medical charity in hospitals. It was widely quoted in the press. Now the Committee has computed the average individual contribution of the attending physicians and surgeons in Westchester hospitals, and found that each of 408 staff attendants in the county contributed services to the value of \$4,553.61 of the total contribution of \$1,857,873 worth of free medical and surgical service. The public should not be permitted to lose sight of its debt to the profession, and this credit stands as one of the many reasons why the profession is entitled to determine its own social destiny.

The New Rochelle Police Department is complimented by the *Westchester Medical Bulletin* on the thorough, speedy and efficient manner in which it recently apprehended one Egbert A. Brooks, 38, negro, of New Rochelle. The defendant is now resting in the County Penitentiary and he is also under a \$500 fine levied by Acting City Judge Fallon. Brooks had entered a plea of not guilty when first arraigned, but later changed his plea to guilty on a charge of illegally practicing medicine. He admitted prescribing medicine in tablet form to three women "patients" and collecting fees. He was known to his patients as "Dr." Brooks.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Malpractice—Care of Maternity Case

A few weeks ago a case came before the highest court in one of the nearby states which serves as a very good illustration of the careful application by a court of the exacting rule which governs the liability of a physician in a malpractice action.*

The plaintiff in the case was a young married woman who had made arrangements with the defendant, a physician who had specialized in obstetrical cases for a number of years, to attend her during the delivery of her expected child and to render to her prenatal and postnatal care. When she first consulted him in January, she was about three months pregnant; the doctor saw her regularly at least once a month down to the end of July and the course of her period of pregnancy was uneventful. On August 4, she entered the hospital where the defendant, the following day, delivered her of the child. Her labor was more than ordinarily protracted. It appeared from the evidence in the case that this was her first child and that she was described as being a closely built woman. In the course of the delivery the doctor made an incision in the patient's perineum for the purpose of preventing its rupture. After the delivery the perineum was sutured by the doctor. She remained in the hospital about ten days after delivery and her convalescence in the hospital was uneventful except that a few days after delivery she complained of pain in the region of the sutures which were removed the day before she left the hospital. At that time the doctor examined the incision and found it was apparently perfectly healed. When the patient was discharged from the hospital she was instructed to return to the defendant in a month for examination and check up.

According to the patient a few days after she returned to her home she noticed a discharge of pus from the region where the sutures had been and experienced pain. She claimed to have reported these facts to the doctor by telephone. His recollection, however was that no such complaints were made at this time, but the patient did return to the doctor's office several times during the following two weeks and was told to wait until a later date for further examination.

On September 14 the doctor examined the patient at his office. At that time the incision

in the perineum was apparently healed. He observed what was described as being a dimple on the skin at the lower end of the incision. He was unable to insert a probe at this point and as she complained of pain and tenderness in the region of the sutures, he directed her to return for another examination in a few weeks.

The patient came back to the doctor on October 9, and at that time examination revealed a small sinus opening at the point where the "dimple" had been which was about the size of the lead in a pencil. With a fine probe the doctor was able to follow the opening for approximately three-quarters of an inch and it appeared to extend no further. He irrigated the condition and curetted it and touched up the edges with silver nitrate. Four weeks later she came back to his office again but at that time she was so hysterical that he was unable to examine or treat her so he told her to come back in a short period of time. The patient's version of that visit was that she was told by the doctor that he did not know what to do about her condition and that he believed the condition to be incurable. The doctor denied that any such conversation took place.

She did not return to the doctor thereafter but, instead, on November 9, consulted a certain Dr. R., who upon examination found the same sinus condition, treated it in much the same manner. Dr. R. at the end of the month performed an operation upon the patient and excised the sinus tract. It however did not heal. After about five months Dr. R. performed the second operation for the purpose of removing the condition which was then present, which he found to consist of a true fistula, leading into the rectum. After that operation the condition healed and the patient recovered rapidly.

The patient brought suit against the defendant in which she charged that his treatment of her had been improper. She made the specific claim that when the defendant was informed by her shortly after she left the hospital of the pain and discharge from which she was suffering, he was negligent in not calling upon her immediately and observing her condition more promptly than he did. She claimed that as a result of the delay the sinus developed into a fistula and it became necessary for her to undergo the two operations.

* Green vs. Stone, 176 Atl. 123

When the case came on for trial plaintiff introduced evidence to the effect that the proper care of the case required the defendant to see the patient more promptly after being told of her condition shortly after she left the hospital. The medical testimony in the case was uncontradicted, that proper practice in the treatment of the condition of the plaintiff at that time required irrigation and cauterization for the purpose of preventing the necessity of resorting to surgery. Testimony did not show whether such treatment, if it had been more promptly applied, would have had any appreciable effect on the result. Dr. R., the physician who performed the operations after the plaintiff left the care of the defendant, was called as a witness in the case by the plaintiff and gave testimony to the effect that sometimes the sinus, such as was present in the case, heals up with office treatment by irrigation and cauterization and that sometimes such treatment would effect a cure of the condition. He also gave testimony to the effect that while a sinus may be cured without surgery a fistula rarely could be cured without surgery.

A certain Dr. S., called as an expert witness by the plaintiff, admitted that it was impossible to say definitely whether irrigation by antiseptics could have cleared up the condition in question. He gave testimony to the effect that a sinus can be better treated in its early stages than at an advanced stage. He also said that it was impossible to say whether the use of washes, hypodermic syringes, and silver nitrate would have been sufficient to have cured the patient.

From the testimony upon the trial it was impossible to ascertain how long the fistula had existed, or what was the earliest date it might have been discovered. There was no basis for determining upon competent testimony how long the sinus had existed before October 9, the date when the defendant found it.

At the conclusion of the testimony the issues were submitted to the jury and the verdict was found in favor of the plaintiff. The Trial Court ruled that the verdict should be set aside on the ground that there was no evidence which showed that plaintiff's injuries were caused by an act or omission of the defendant. The plaintiff took an appeal from the ruling of the Trial Court.

The Appellate Court, in the course of its opinion, affirming the ruling of the Trial Court, set forth the rule governing the liability of a physician under the circumstances as follows:

One who holds himself out as a specialist in the treatment of a certain organ, injury or disease . . . is not to be judged by the result, nor is he to be held liable for an error of judgment. His negligence is to be determined by reference to the pertinent facts existing at the time of his

examination and treatment, of which he knew, or in the exercise of due care should have known. It may consist in a failure to apply the proper remedy upon a correct determination of existing physical conditions, or it may precede that and result from a failure to properly inform himself of these conditions. If the latter, then it must appear that he had a reasonable opportunity for examination, and that the true physical conditions were so apparent that they could have been ascertained by the exercise of the required degree of care and skill, for if a determination of these physical facts resolves itself into a question of judgment merely, he cannot be held liable for his error.

The Appellate Court pointed out that the plaintiff had failed to establish a valid case entitling the plaintiff to damages against a physician stating in part as follows:

The proper treatment of a condition such as claimed by the plaintiff and the probability of effecting a cure by various methods present questions requiring the special experience of expert witnesses. It is a field requiring special skill and learning, wherein it is not permissible for laymen as non-experts to set up any artificial standards as to methods of treatment or probability of cure. The duty rested upon the plaintiff to produce testimony before the jury to the effect that the earlier treatment of the case with reasonable probability could have aided the patient. As the testimony goes no farther than to state that earlier treatment might have been beneficial, the jury was left purely to speculation as to whether the conduct of the defendant was a cause of the plaintiff's subsequent condition; and under the circumstances, the court did not err in setting aside the verdict.

Treatment of Sty

A man consulted a physician, who had for many years specialized in treatment of the eye, ear, nose, and throat diseases, complaining of a painful condition of his right eye.

The doctor examined him and found a sty present and infiltration of the upper lid. The doctor thereupon lanced the sty with a sterile knife and gave the patient a preparation of silver with instructions to apply the solution to his eye every two hours and return the next day for a further examination.

According to the doctor his knife did not come into contact with the patient's eyeball during the operation. The patient did not return as instructed and the doctor never heard anything further from him until he received a letter from attorneys threatening suit on behalf of the patient. The claim was that the doctor in treating the eye had scratched the eyeball.

A suit was instituted against the doctor to recover damages for alleged malpractice and the plaintiff made the specific claim in his pleadings that the defendant so carelessly conducted himself in removing the sty that he scratched the cornea of the eye and left

the eye in that condition without the application of any antiseptic and without further treatment. The plaintiff claimed that an infection developed resulting in a small ulcer and infection on the lower lid and that he underwent treatment for over a month. He, however, claimed no permanent loss of vision.

When the case was reached for trial on the calendar of the court, the plaintiff's attorney showed no inclination to try the case and after some time had elapsed and the defendant's attorney had made it clear that there would be no offer of settlement, the plaintiff consented to discontinue the action.

Removal of Semilunar Cartilage

A man who was employed as a bricklayer while engaged in the construction of a building fell from a ladder and received contusions and abrasions of the knee.

Emergency treatment was provided him by his employer and he was referred to a surgeon for examination. The surgeon diagnosed the condition from which the man was suffering as a dislocation of the semilunar cartilage of the knee and suggested an operation.

An operation was performed for the purpose of the removal of the semilunar cartilage and a cast was applied on the leg from the foot to the thigh. The patient remained in the hospital from four to five weeks under the care of a doctor. A week after he left the hospital the cast was removed by another physician.

The surgeon kept in touch with the plaintiff for a period of several months and examined him from time to time and directed him to return to the hospital on about six occasions for the purpose of placing him under ether and manipulating the knee. At the time the doctor last saw the patient he was walking without cane or crutches and his leg could be flexed at an angle of nearly 45°.

An action was brought against the doctor, in which the claim was made that the defendant's treatment of the case was improper and that as a result the plaintiff was caused to suffer loss of function of the knee and inability to pursue his usual vocation.

When the case was reached for trial the plaintiff was not ready to proceed and the case was marked off the calendar. After some time had elapsed an application was made to the court to dismiss the action for failure on the part of the plaintiff to prosecute the same. The said application was granted, thereby finally terminating the action.

Treatment of Carcinoma

A specialist in surgery was consulted by an interne whom he had been acquainted with for some time with respect to complaints of abdominal distress. The doctor examined certain x-ray pictures that had been previously taken of his intestinal tract and found that they indicated a lesion of the colon. The doctor upon manual examination found a mass in the right upper quadrant and suggested an exploratory operation.

The operation was arranged, preparatory to which it was necessary to administer a blood transfusion. A right upper trans-rectus incision was made and the doctor found a large nodular mass involving the transverse colon and extending up to the liver. He examined it grossly and without making a biopsy determined that the condition was an inoperable carcinoma. The abdomen was then closed and the patient improved satisfactorily and in two weeks was able to leave the hospital. The surgeon advised no further operation for he felt that to disturb the mass he found on making the exploratory operation would accomplish nothing except to hasten the patient's death.

Some time after an action was instituted against the surgeon based upon the claim that the defendant was negligent in treating the case as one of an inoperable carcinoma, and that his diagnosis was incorrect and that it prevented the plaintiff from obtaining adequate remedial treatment for his condition. Subsequent events, however, indicated that the defendant's diagnosis was undoubtedly correct for after the case had been pending only a few months and before it could be reached for trial the plaintiff died, thereby abating the action.

FOR THE OVERWORKED DOCTOR

A tired person is an inefficient person, no matter what sort of work he is doing or what it is that has tired him. Emotional and mental strain will, in many, produce fatigue faster than will physical effort. Physicians, being human, must be included in this generalization, says *Clinical Medicine*.

In these days, when many duties press upon us, it is not always possible for the truly busy people to obtain as much sleep

as they really need, so it becomes increasingly important that we should learn the art of relaxation, in order that we may take our rest in small installments, for it is strain, rather than actual labor, that exhausts most of us unduly.

We all need to learn how to relax the body and the mind for brief intervals, and this is an art which can be taught by books and learned by sincere and regular practice.

Books

REVIEWED

Postures and Practices During Labor Among Primitive Peoples—By Julius Jarcho M.D. Octavo of 175 pages, illustrated. New York, Paul B Hoeber, Inc., 1934. Cloth, \$3.50

An attractive volume illustrated on almost every page. Engelmann has been freely drawn upon of course, and many drawings of Witkowski and Felkin, not nearly so well known, but just as interesting as Engelmann's, are included. The author's interest in the pelvic girdle is in evidence throughout, his purpose is the stimulation of modern obstetricians, so that they may see the advantages of physiological posture in assisting the forces of labor. Jarcho has assembled some very interesting material.

CHARLES A. GORDON

Corrective Physical Education—By Josephine L. Rathbone M.A. 12mo of 292 pages, illustrated. Philadelphia, W. B. Saunders Company, 1934. Cloth, \$2.50

The chapters on "Anatomy and Physiology" are exceptionally good for this type of work.

The book builds up its theme from the normal to the abnormal in a logical manner. Included are the early indications of diseases causing deformities. The psychological effect of deformities is well presented. The summary of cardinal principles of body building is excellent.

The author throughout shows definitely a concept of the entire problem of a well body as a whole and has not lost sight of the whole problem because of concentration on the corrective side of treatment and prevention.

KENNETH T. YOUNG

International Clinics—A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 3. 44th Series 1934. Louis Hamman M.D., Editor. Octavo of 327 pages illustrated. Philadelphia, J. B. Lippincott Company [c 1934]. Cloth, \$3.00

In the section on Medicine some of the subjects discussed are "The Heart and Athletics," "Addison's Disease," "Allergy," and "Functional Symptoms in Relation to Organic Disease." Maud E. Abbott contributes an extensive discussion on the "Differential Diagnosis of Congenital Heart Disease."

In the surgical section, "Cancer of the Stomach," "Functional Uterine Hemorrhage," "Hypertthyroidism," and "Water Balance in Surgical Conditions" are among the subjects treated. In the treatment of acute intussusception, the conservative treatment by warm water injections is described and regarded with favor. There is a report from the Johns Hopkins Hospital of a clinical pathological conference on Hematemesis and other articles of much practical interest.

W. E. McCOLLUM

Essentials of Infant Feeding and Paediatric Practice—By Henry P. Wright, M.D. Octavo of 212 pages. New York, Oxford University Press, 1934.

The author has compiled a small volume of data concerning the proper diet for infants and children. Detail is omitted. Short paragraphs on each subject is the rule so that one may almost at a glance get the meat of the subject at hand. In looking through the book one gets the idea that brevity is overemphasized in some of the chapters.

THURMAN B. GIVAN

A Text Book of Pathology—Edited by E. T. Bell M.D. Second Edition. Octavo of 767 pages illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$8.50

The second edition of this text book has been revised the chapters enlarged and recent advances in pathology have been incorporated into the text. There is a new chapter on diseases of the bones and joints. The chapter on diseases of the kidneys is particularly good. Gynecologic and obstetric pathology is presented more fully than in many other works of one volume. The chapters on diseases of the spleen, nervous system, and the blood also deserve special commendation.

There are more references to the literature and after many of them are explanatory notes on the subjects

of the articles. This should be very helpful in selecting advanced reading. The illustrations are chiefly photographs of original specimens and are good.

The contributors are L. T. Bell, H. J. Clawson, Hal Downey, J. S. McCartney and C. J. Watson, all of the University of Minnesota.

F. B. SMITH

Bronchoscopy Esophagoscopy and Gastroscopy—A Manual of Endoscopy and Laryngeal Surgery. By Chevalier Jackson M.D. and Chevalier L. Jackson, M.D. Third Edition. Octavo of 485 pages illustrated. Philadelphia, W. B. Saunders Company, 1934.

Dr. Jackson's new book fulfills the present day need on this subject, not only on account of the great advances that have been made in foreign body work, but also because of the ever broadening field in diagnosis and treatment of disease of the trachea and bronchi. It has been condensed by omitting the developmental stages by which the fundamentals of this specialty were determined.

The new sections that have been added on gastroscopy and diagnosis and treatment of disease of the trachea and bronchi, make the book an invaluable aid, not only to the specialist but to the general practitioner as well. It is profusely and beautifully illustrated. Many of the plates are new and in color by the author.

JOHN AUWERDA

Mothers' Guide When Sickness Comes—By Roger H. Bennett M.D. and Edward T. Wilkes, M.D. Octavo of 400 pages. Garden City, N. Y., Doubleday, Doran & Company, 1934. Cloth, \$2.50

While many books have been written to aid in educating mothers how to recognize the need for consulting doctor in the care of their babies or children, most have fallen short in their objective. In a large city many physicians object to having their individual families buy these books on the ground that there may arise conflicts to their own teaching, and thereby the mother becomes more befuddled than ever. There is a great deal of truth in this statement yet so few physicians take time to point out for instance, how and when to bathe a baby, how to prepare a baby for winter, how to prevent the spread of a contagion and thousands of other questions that run through the mother's mind daily, that a book such as the authors have compiled should be used by thousands to good advantage, especially by those in remote places. They point out it is not the purpose to supplant the physician. The book is well done and very complete.

THURMAN B. GIVAN

Experimental Physiology—By Sir Edward Sharpey Schafer, F.R.S. Fifth Edition. Octavo of 168 pages illustrated. New York, Longmans Green & Company, 1934. Cloth, \$2.20

This fifth edition of Schafer's *Experimental Physiology*, revised with the help of W. A. Darr follows the general mold laid out by the previous editions, with its emphasis on the collection of fundamental physiological data. It contains all of the time honored experiments and also some of the more recent ones on such subjects as the carotid sinus reflex and other heart reflexes. No attempt however, has been made to follow the newer trend in the direction of experiments in human physiology, almost half the manual being devoted to muscle nerve physiology.

The experiments are concisely and adequately presented and are supplemented by numerous simple diagrams of the apparatus used.

DAVID I. ABRAHAMSON

The Dangerous Age in Men—A Treatise on the Prostate Glands. By Chester T. Stone, M.D. 12mo of 105 pages. New York, The Macmillan Company, 1934. Cloth, \$1.75

This little book is a discussion of sex life, particularly in the male and the functions and physiology of the prostate in the ageing male. It is written for the lay and presents a delicate subject with reasonable restraint.

N. P. RATHBURN

Human Sterility.—Causation, Diagnosis, and Treatment. A Practical Manual of Clinical Procedure. By Samuel R. Meaker, M.D. Octavo of 276 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1934. Cloth, \$4.00.

Doctor Meaker's book of 264 pages is a well-written presentation of the routine investigation given sterility problems by a group working under his direction. It describes in detail the medical, urological, and endocrinological aspects of the subjects as well as the gynecological procedures and treatment. Certain details of study have been carried to a degree which is frankly experimental and without proved diagnostic importance. The routine passing of the urethral sound in the male, blood chemistry, counting of blood platelets, systematic determination of vital capacity, instillation as well as insufflation of the tubes, sugar tolerance test, and the like, will be considered impracticable by many readers.

The rôle of the endocrines in fertility has been extensively discussed, but the correlation of blood and urine hormone determinations with ovarian function is singularly omitted. Many deductions drawn as to the importance of clinical signs and symptoms in the realm of glandular disease and the relation of the latter to failure of conception will not be accorded universal acceptance.

The student of fertility will find much of value in this book; the data has been carefully assembled and in a way to heighten the readability of the text. A somewhat dogmatic style doubtless adds to the teaching force of the contribution, and, concerning the controversial points the reader is left to his own conclusions.

WM. H. CARY

Influenza.—By David Thomson & Robert Thomson. Quarto of 916 pages. Baltimore, Williams & Wilkins, 1934. (Volume X, May, 1934 of the Annals of the Pickett-Thomson Research Laboratory. Monograph XVI, Part. II.) Paper, \$17.50.

This part completes the large monograph of 1557 pages and furnishes a complete study of influenza in all its phases. The bibliography alone contains over 4,500 references and occupies 101 pages. In this part, all the complications are discussed, such as the respiratory, ocular, nervous, aural, cardiac, and gastro-intestinal.

Opinions as to gastro-intestinal influenza occupy 75 pages. The exact nature of this form is concluded to be obscure and the relation to the predominant respiratory type undetermined.

The effects of the disease upon the heart and circulatory system are of much interest. The authors state that "there is considerable evidence to indicate that the virus of influenza inflicts, in many cases, a direct damaging effect on the cardiac and circulatory structures." The influenza toxin may perhaps act directly on the cardiac muscle, but generally the toxic influence is believed to be limited to the cardiac nervous apparatus. Cases of primary endocarditis, myocarditis, and pericarditis have been recorded, although somewhat rare; more usually these develop as a result of mixed pyogenic infections associated with secondary lung complications.

According to Sansom and to Mackenzie, influenza never produces any disease of the heart even remotely resembling the rheumatic heart.

This is an extremely valuable reference book, the most complete of its kind ever published and fills one with admiration for the industry exhibited and the result achieved.

W. E. McCOLLUM

A Text-Book of Pathology.—An Introduction to Medicine. By William Boyd, M.D. Second Edition. Octavo of 1047 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$10.00.

It is quite in keeping with the merit of this book that a second edition should have been issued within so short a time. It would be impossible to review in detail the contents of the volume. As a text-book of pathology it stands in a class by itself. It may be

criticized, perhaps, for the brevity with which some subjects are considered. But this is compensated for by the references at the end of each chapter. The illustrations are exceptionally apropos to the text and are exceedingly well done. The views expressed are safe and sound.

This book should prove exceedingly valuable to the student and general practitioner, and may even be used with great profit by the specialist in tissue pathology. The scope of the work is particularly complete and covers every subject with which the pathologist comes in contact.

Dr. Boyd has again scored a complete victory with the presentation of *A Text-Book of Pathology* to the medical public.

MAX LEDERER

Industrial Maladies.—By Sir Thomas Legge, M.D. Edited by S. A. Henry, M.D. Octavo of 234 pages. New York and London, Oxford University Press, 1934.

There are very few medical practitioners today who do not come in contact directly or indirectly with problems incidental to industrial diseases. An authority in this field, therefore, as is Dr. Legge who writes this volume, is worthy of special attention.

From a long experience in England in this field, the author discusses various diseases, notably those which are the result of poisons such as arsenic, lead, mercury, and benzene and its homologues.

An interesting chapter to physicians is that of industrial dermatitis, for these are conditions commonly encountered in general practice. Another chapter discusses industrial pulmonary disease caused by dust.

As most physicians are watching closely the development of workmen's compensation laws in the United States, it is possible to compare the trend in England in this respect as noted in a chapter on this topic.

ALFRED E. SHIPLEY

Conception Period of Women.—By Dr. Kyusaku Ogino. English Translation by Dr. Yonez Miyagawa. 12mo. of 94 pages. Harrisburg, Pa., Medical Arts Publishing Company. [c.1934]. Fabrikoid, \$1.00.

The researches of Ogino and Knaus are of course well known to gynecologists, and the public has already been informed that there is in every menstrual cycle a sterile period in which conception is impossible. A previous book on this subject enjoys a very wide circulation for its practical application is obvious. Now Ogino himself has prepared a brochure for popular study.

That there is a sterile period has long been known, but how to determine its exact time in the cycle has been the difficulty. Ogino and Knaus have arrived at approximately the same conclusions by very different methods.

Although not positive, it appears that the maximum span of life of the spermatozoon is less than three days, and there is excellent evidence to show that it loses its power of fertilization long before this. That the ovum survives for less than one day is almost certain. If we assume that ovulation bears a definite time relation to the next period, the problem becomes clear, and the solution is not difficult for all those whose cycles are fairly regular. Menstruation is but the result of ovulation, although Hartman will not admit this. Ogino is certain that the conception period is in the eight days from the twelfth to the nineteenth day before the next menses.

An excellent and very practical book. Because it is not written in the form of questions and answers it may not have the popular appeal of another well-known book on the same subject. This is authoritative, however, as Ogino himself is the author. It is too bad that the publishers have bound within its covers their own blurb on the front page, and a bid for volunteer book agents on the last. It reads: "Men and women who want to be agents and sell this book, should write to the publisher. Married women may work in their spare time, and earn a nice weekly income. Write for details."

CHARLES A. GORDON

Medical Broadcast

The following radio talk has been scheduled under the auspices of the Medical Information Bureau of the New York Academy of Medicine from Station WABC, C. B. S.: Thursday, March 7, 11:15 A.M., 15 minutes.

Subject: "Heart Disease in Children and Young Adults."

Speaker: Dr. Robert L. Levy, Director of the Heart Department, Columbia-Presbyterian Medical Center, New York City.

PSYCHIATRY AND THE GENERAL PRACTITIONER**Syndromes Commonly Met with in Practice**

MORTIMER W. RAYNOR, M.D.

WHITE PLAINS

Psychiatry as a special branch of medicine did not exist a hundred and fifty years ago. The practitioner of the day treated the psychiatric problems which came to him with the same relative understanding as he treated other medical problems. In our own State it is interesting to note that in 1792 psychiatric patients were sent to the New York Hospital by the attending physicians who continued their treatment in the general wards.

Because of certain practical difficulties especially with excited patients, psychiatric patients were provided for in separate institutions instead of in general hospitals. This separation of the patients into a special group removed them from the practicing physician and his interest waned. With the coming of Virchow and his cellular pathology the contact appeared to be completely broken. In the early part of the last century with the advent of separate provision for psychiatric cases, the study and treatment of these disorders was confined almost wholly to physicians in asylums and mental hospitals. By 1880 there again began to be a revival of interest in psychiatric problems by the profession generally. Since then psychiatric medicine has gradually taken its place beside general medicine.

Dr Van Etten¹ in an address, said of the physician in general practice

Let him study mental diseases whose victims fill forty two per cent of all hospital beds.

Let him study the fields of personality, of endocrinology, of social maladjustment, of eugenics of psychiatry and of the prevention of mental diseases where he will find much employment profitable to himself and our heavily burdened tax payers.

Any attempt to estimate the extent of the problem will at best give only an approximate answer. Reference to certain available data will however give a clue to the size of the problem and to estimates of its importance.

In 1932² there were nearly 50,000 patients cared for in New York State hospitals at an expense of approximately nineteen and a quarter million dollars. In the same year there were in round numbers 11,000 new patients admitted to the State hospitals.

Ziegler³ in 1931 made an inquiry of more than a hundred physicians mostly in general practice in the vicinity of Albany, and reported that about 20 per cent of the patients who consulted them had no bodily disease and, that each doctor sent on an average of 7 patients to a State hospital each year. The National Committee for Mental Hygiene⁴ made inquiries of 683 physicians who estimated that 35 to 40 per cent of their cases had very definite psychiatric factors which it was necessary to take into consideration in their treatment. Moersch⁵ reported that about 40 per cent of the patients admitted to the Mayo Clinic in 1927 had psychiatric disorders or psychiatric complications of the illnesses for which they were treated at the Clinic. It is apparent from the above that psychiatric problems assume considerable importance to the profession when it is realized that these patients consult a general physician first about their illness.

The attitude of physicians to psychiatric problems is of much importance. Ziegler³ in his study found that the doctors expressed their interest as follows:

	No interest	Slight or moderate interest	Great interest
In nervous patients (95).....	12	55	28
In mental patients (93).....	25	56	12

A survey⁶ made in the metropolitan district of New York City (including Westchester County and neighboring communities of New Jersey and Connecticut) showed that the physicians of Westchester County were better informed and more interested in psychiatric disorders than the other physicians of the metropolitan district. This is undoubtedly due to the regular psychiatric meetings for physicians of the community held at Bloomingdale Hospital over a period of a number of years.

An analysis of the first admissions to State hospitals (1932) shows that 45 per cent, or about 4,800, are suffering from organic psychoses—psychoses in which there is demonstrable anatomic involvement of brain tissue. This group for purposes of discussion may be divided into three sub-groups: Group I which comprises the traumatic, cerebral arteriosclerotic, acute and chronic infections of the brain, toxic states, and those associated with other somatic disorders, were definitely under treatment by the general practitioner before they developed their psychiatric complications. Group II comprises the alcoholic group which in addition to being medical and psychiatric problems has important social implications. The senile psychoses and the psychoses associated with certain other diseases of the central nervous system comprise Group III and will only be mentioned here.

Group I, comprising 31 per cent of the total admissions, is directly the problem of general medicine, and prevention and early treatment of these cases must be accepted as such. They only become psychiatric cases when they have passed out of hand of general medicine. It should not be assumed that psychiatric medicine has nothing to contribute to these problems because they already have much to offer in the prevention, diagnosis, and early treatment.

The alcoholic disorders may be looked upon as joint problems of general and psychiatric medicine; the former because they come to them first, and the latter because they are better understood and treated since psychiatric medicine understands and deals more particularly with psychological and social maladjustments.

Psychiatry has much to contribute to general medicine in the understanding of this entire problem.

The general physician has always recognized with great astuteness the somatic signs of organic brain and nervous disease but has not been as familiar with, nor has he used to advantage, the psychic signs of brain involvement.

Rather than discuss the diagnostic groups separately it seems opportune to discuss psychiatric organic mental reaction types to the end that the organic features may be separated out and identified from those symptoms which are, more strictly speaking, functional or personality reactions.

The psychiatric organic reactions may be grouped as acute, subacute, and chronic types. To the acute reactions belong the stupors—delirious and acutely confused states which are named in order of the depth of their reaction. The measure of these is the level of the threshold of awareness to their surroundings. The sick patient who has no brain involvement is perfectly clear as to his surroundings throughout his illness. The patient with brain involvement varies much from minute to minute and hour to hour in his awareness to his surroundings and his ability to take in impressions.

The elements, then, of the acute organic mental reaction are: (a) *constant variation of the level of the threshold of awareness*; as the threshold raises the patient is less able to clearly take in impressions and may become disoriented, and as it goes lower apperception becomes more clear; (b) *variation of attention*; (c) *impaired retention* of incoming impressions leading to *defects of memory*; (d) *impaired activation* of trains of thought in relation to stored memories of past mental processes which leads to scattering and fragmentation of the train of thought; (e) *impaired elaboration* of thought processes in ideation and new trains of thought; this in turn gives rise to confabulations and also to phantasies and ill-defined delusional formations; (f) *diminution of mental tension* and mental capacity; (g). *speech defect* giving rise to slurring and paraphasia; (h) *illusions and hallucinations* of which the visual are the most characteristic but which may also be of hearing, smell, taste, and common sensations; (i) *an affect or feeling of fear*, sometimes of pleasure; and (j) *restlessness and mumbling*.

It is hoped that the foregoing delineation is recognized as an analysis of the picture of toxic or infective delirium.

The clinical picture varies in accordance with involvement or impairment of the above components of the reaction. Whether a case is one of partial stupor, delirium, or confusion depends upon the degree of impairment of, first the level of the threshold of awareness, and next of the variation of the other components. The importance of studying the clinical picture in detail is that any one of these symptoms may appear first and there may be any combination of them. Any one of these may be the first sign of ushering in an extension of the disease, a complication, or actual serious brain involvement.

It is important that they be watched for with a great deal of care. The slightest variation of awareness, drowsiness, or inability to grasp what is said, or misinterpretation of familiar objects or sounds, or slips of speech, or changes in affect, may be important signals of approaching danger, such signals will often give warnings of one to twenty four and forty-eight hours in advance. The recognition and accurate interpretation of these symptoms assist in making an accurate and early diagnosis. They assist in the differentiation of various organic diseases, and of organic and the more severe functional psychoses, also they give indication for treatment and help provide a basis for prognosis.

The need of reviewing this situation in both general and psychiatric practice is evident when we consider that frequently it is not until the full picture of delirium or confusion has developed some time later that the real situation is grasped. At this point it seems desirable to point out that functional and somatic disorders may be present simultaneously, and that each of them may color and at times obscure the picture of the other, also that it is more the custom in practice today than formerly to prescribe hypnotics more frequently. Patients learn the name of the drug prescribed and continue to take it for a longer period or in larger quantities than the physician is aware. The continued or excessive use of drugs often gives rise to what apparently are alarming symptoms in the course of their treatment and these are not infrequently misunderstood as the symptoms of one of the major psychoses.

The case which immediately follows is an illustration of the foregoing.

CASE I—A man aged 59 with moderate arteriosclerosis and heart and renal involvement, who was worried on account of loss of money, and drank moderately but daily, developed an acutely strangulated hernia. He was given morphin before leaving home for the hospital where he was operated upon at once. *He had no clear recollection of events after that time* although he appeared 'normal' to those about him. Six days after the operation he became delirious and some infection was found in his wound. During the next month and a half he continued delirious or confused and was noisy and restless for which he received drugs hither to as follows: Sodium bromide, 40 gr., codain 2 gr., chloral hydrate, 20 gr.—three times daily. In addition he received paraldehyde in ounce doses. His speech was thick and there was marked incoordination in the movement of his hands. His case was diagnosed after one and a half months as "alcoholic dementia and probably senile dementia."

This case presented the picture of an acute organic mental reaction from the beginning. Unclearness developed following the initial dose of morphin and from that time on he did not take in fully what was going on about him (threshold of awareness raised). Following the operation he was said to be "normal" for a week but did "say some queer things" (Inability to activate memories and to elaborate trains of thought into normal or rational thinking). After recovery he could not recall except hazily here and there anything that had happened during the week he was said to have been "normal" (impaired retention and memory). During his delirious period he was inattentive (high threshold of awareness), his talk was rambling and he expressed vague disconnected dreamy delusions and he attempted to pick up the physician's thumb which was resting on the table and referred to it as a cigarette (impaired activation and elaboration).

A study of the details of the clinical picture indicated an acute reaction toxic delirium with a good prognosis. Following his admission to Bloomingdale Hospital all medication was withdrawn the gastrointestinal tract was thoroughly cleared continuous warm baths were administered and fluid nourishment was forced. His mental condition cleared gradually. He passed through a period in which he partially grasped his surroundings but fabricated statements and only upon close scrutiny were they found to be phantasied stories based on events which fitted in with his previous experience but which were contrary to the actual facts. His manner was so natural that at times his family thought him normal. Two months after the medication had been stopped he became perfectly clear. He had an amnesia for the greater part of his illness up to that time. He understood that he had had a delirious period. There were no residuals of any mental deterioration and he was later discharged as recovered.

CASE II—A young man with a long standing heart lesion worried over his work and following an unusual exertion developed symptoms of cardiac decompensation with pain which lasted for weeks for which he was given moderate

doses of digitalis. About the middle of his illness he began having "nightmares" several times daily (onset of acute mental reaction) in which he saw vapors, red and black spots, and bugs in the room. At the same time he heard voices speaking and all sounds were exaggerated. Following an attack of diarrhea with a temperature of 102 he said his brother who was caring for him had killed two people in the bathroom, that meat served with his meal looked like a baby's face. He finally developed a great fear of being killed and became so disturbed that he was removed to Bloomingdale Hospital with the diagnosis of an "undetermined psychosis." Here he was restless, getting in and out of bed, looking behind the door and into bureau drawers, and showed varying degrees of confusion from partially grasping his surroundings to disorientation. He presented illusions and hallucinations of sight and hearing. He fabricated stories which appeared so rational that his family were at these times inclined to regard him as mentally well; then he would wander off into his phantasies and dispel their opinion. This condition continued even after his physical condition permitted him to be about and out of doors. The auditory hallucinations, hearing voices of people talking about him, were the last to clear up. Cardiac compensation was established, the digitalis was stopped, elimination was promoted, and a light-fluid diet was prescribed. One and a half months after admission he was discharged recovered from a toxic delirium. The auditory hallucinations which persisted after all the other symptoms cleared up were evidently reactions of his personality and not dependent entirely upon the toxic factors.

In this case despite the variation in the level of awareness the defective elaboration, the type and persistence of the hallucinations, the frequent naturalness of his behavior and talk were such that a diagnosis of functional psychosis was suspected. Yet a careful observation of the clinical symptoms indicated clearly that we were dealing with an acute organic mental reaction with a good prognosis. The variability of the threshold of awareness and the defect of elaboration were evident throughout the illness.

CASE III.—A man in the early sixties, with a college education, had been nervous for about a year. He suffered an automobile accident and was picked up and removed to a hospital in a semi-conscious condition with lacerations of scalp and many bodily bruises. At first he was semi-conscious, disoriented and restless. The diagnosis of laceration of the brain was made. The case record disclosed that he was "confused, restless, and at times irrational. He could not follow prolonged discussion and spontaneous statements were confused. He complied with minor requests and knew the month and the city in which he was under treatment. He tired almost immediately."

One month later his physical condition became so satisfactory that he returned home. Upon reaching home he promptly became confused,

restless, and noisy, for which drugs were given. The diagnosis was now made of intercerebral hemorrhages with edema. The subsequent course led to the opinion that a senile dementia had been initiated.

A week after his return home he was admitted to Bloomingdale Hospital where he presented the clinical picture of an acute organic mental reaction of the acute confusional type. All medication was stopped, the gastrointestinal tract was cleared, fluid nourishment was forced, warm, wet packs were administered, and a lumbar puncture showed some intracranial pressure which was relieved. The patient made an uneventful recovery in about three months. He had some spasticity of the extremities of the opposite side.

The acute confusion which developed in this case following his journey home was undoubtedly a fatigue reaction. It was interesting to note the return of the organic mental symptoms during the early part of his convalescence whenever he became fatigued. Two years after discharge from the hospital he was examined and found to be quite well mentally.

The prognosis of an acute delirious reaction is generally good when all the signs are present and the somatic or toxic disorder is not progressing or is indefinite and if the mental reaction is out of proportion to the physical signs. In the presence of increasing definite somatic disease the prognosis is not so favorable. In head injuries the prognosis is better with a delirious reaction without septic fever than with a continued stupor. Administration of drugs for restlessness is often an added cause of the delirious reaction and may become the sole cause of its continuation. Delirium with septic fever may indicate the onset of a meningitis or abscess. The prognosis of acute delirious reactions due to drugs is almost uniformly good.

The acute types of reactions seen in cerebral arteriosclerosis are generally of good prognosis. Acute reactions occurring early in heart and kidney disease are not of bad prognostic import provided prompt treatment is instituted. Variations in the clinical picture with the greatest impairment in the fields of retention and of elaboration are less favorable for a complete return to the normal mental state and the prognosis should be guarded especially when the progress is unusually slow. The organic mental reactions of the acute confused type are generally of reasonably good prognosis with the same limitation as the delirious reaction. It resembles the delirious reaction except the threshold of awareness is lower and hallucinations are less in evidence. Short delirious episodes or occasional hallucinations with fear sometimes occur. The term, confusion, as used

here is in reference to the level of the threshold of awareness and orientation, rather than to confusion of thought, which is so often not differentiated.

The subacute organic mental reaction types may begin as such or they may develop out of an acute reaction. The range of variation in symptoms which may be included in the subacute reactions is quite extensive. The most typical symptom of this type of reaction is acute confabulation. It is also spoken of as Korsakow syndrome. It will be recalled that Korsakow first described this syndrome but thought it was always associated with polyneuritis and alcohol. It is definitely found as an organic mental syndrome and by no means always associated with alcohol. It is found in infective-exhaustive-toxic states as well as other organic states.

In this reaction the threshold of awareness is not disturbed but there is a marked retention defect which interferes with the elaboration of impressions and an amnesia or memory defect which may be patchy or complete for a more or less definite period. The confabulations may be wholly phantastic or may be along familiar or habitual lines and are sometimes referred to as "opportune confabulations." Because the threshold of awareness is not disturbed the patient appears clear. The retention defect does not permit him to fix impressions and there is a defect in the activation of past memories. As a consequence he elaborates in an entirely phantastic manner and fills in the gaps of actuality by fabrications.

The subacute reactions are not necessarily of bad prognostic omen but certainly should be viewed with suspicion if they are prolonged. Severe and prolonged infective-exhaustive-toxic states have however been seen which have continued for several months with ultimate recovery. They may be prolonged or recur if the patient has been injudicious regarding the amount of activity undertaken; rest is essential to their recovery. There may be delirious features in the early stages. The prognosis is better when there is associated unclearness. In the more severe reactions there develops a permanent memory defect. Drugs and alcoholic intoxication may bring about this type of reaction. These reactions often follow operations and acute infections in the presence of cerebral arteriosclerosis.

The chronic organic mental reaction

types are evident enough in the well marked case. It is the mild case which is sometimes difficult to establish. It is apparent that the threshold of awareness is unimpaired, the patient is clear but his retention is impaired. Sometimes patients very cleverly cover up the defect but a few simple tests will uncover the difficulty. Elaboration of gross impressions or ideas are reasonably good while those impressions or ideas on which concentration is necessary are found not to be elaborated. Attention, concentration, and the general mental capacity are impaired and a memory defect of a greater or lesser degree is present. It is generally diffuse or patchy. There will also be found a general let-down in their attitude toward personal appearance, the usual social conventions, responsibilities and moral situations.

The most usual causes are senile states which have a strikingly special type of memory defect for recent events, cerebral arteriosclerosis, brain syphilis, alcoholism, and severe and prolonged toxic disorders. Carbon monoxide poisoning which has been so frequent of late is worthy of special consideration. Following the unconscious state the patient may appear for a short time to be doing well and then it is apparent, rather abruptly, that he has changed and an acute, subacute, or chronic reaction is found to be present, any one of which ends in a chronic state of greater or lesser severity. Prognosis should always be guarded. The subsequent symptoms have been known to be deferred for as long as three months.

The alcoholic psychoses group now constitutes about 6 per cent of the first admissions to State hospitals and are again more frequent in hospitals generally. The whole alcoholic question deserves the attention of the profession not as a moral issue, but as a medical problem. To be understood it must be viewed from all angles, physiological, psychological, psychiatric, and social. Psychiatric medicine views the alcoholic disorders in two ways, one as a toxic disorder, and, two, as a functional disorder. Delirium tremens, the Korsakow states associated with polyneuritis, and the deterioration states definitely present the clinical picture of organic mental reactions which may lead to organic deterioration while the alcoholic hallucinosis and paranoias present a functional type of reaction with effects of fear. It should be pointed out, however, that early in these latter

states some elements of the organic type of reaction may be temporarily present. In the hallucinoses the patient is in touch with his surroundings. Voices threaten and accuse men patients of perversions (c. s.) and women of sexual indiscretions. The paranoid trend is prominent.

It is important to note that the onset is different in these two types. In delirium tremens the onset generally follows a period of abstinence, a trauma, or an acute somatic illness. The onset of an acute hallucinosis occurs in the course of a period of drinking and is associated with some emotional stress, loss of job, argument with wife or sweetheart, and so on. One important consideration in differentiating the two types is prognosis. Delirium tremens often results in organic deterioration while in the hallucinoses Kirby⁷ showed that at least 15 per cent of them developed dementia praecox psychoses requiring long hospital residence.

The relation of alcohol to the biogenic or functional psychiatric disorders should be borne in mind. Kirby in his study found that 7 per cent of the hallucinoses had underlying manic-depressive psychoses. Excessive drinking is often associated with the early symptoms of both manic excitements and depressions. The use of alcohol may be associated with the onset of any of the functional disorders.

The subacute alcoholic reactions and sometimes the chronic reactions are associated with confabulations and memory defects. There is found relatively little clouding and few hallucinations although there may be fluctuations in which there may be delirious episodes.

The chronic alcoholic reactions resemble other types of chronic organic reactions with the greater defect in the field of moral judgments. There may be slight memory defects or marked memory defects and gross fabrications associated with polyneuritis.

In all of the organic reaction types it is apparent that there are always several etiological factors at work. In addition to the outstanding causes are auto-intoxication and dehydration. These are produced by failure to receive sufficient nourishment and fluids, failure to keep the gastrointestinal tract functioning, and not to be omitted are sedative drugs given to combat noise and restlessness. The general physician is unfortunately not so prompt to resort to tube feeding as the psychiatrist.

In turning to the functional disorders it is found that they make up about two-thirds of the resident population in State hospitals and about 50 per cent of the yearly first admissions. Notwithstanding this great problem the question of diagnosis and treatment of the so-called nervous or neurotic cases alone or in association with somatic disease is of greater interest to physicians than other types. This must necessarily be so because of their large incidence as shown by Ziegler, Moersch, and the survey of the National Committee for Mental Hygiene. These studies indicated 20 to 40 per cent of patients seen presented psychiatric problems.

In this connection it must not be inferred as the author has pointed out elsewhere⁸ that there is a fundamental difference between the severe or mental and the mild or nervous disorders. The difference lies in the mechanisms of their development.

In evaluating the signs and symptoms of a given case it is essential that a careful study⁸ be made of the constitution and the total life reactions of the patient. Snap diagnoses are sure to lead to errors. Psychiatric disorders are not simple but complex in their makeup. On the other hand by careful scrutiny of the symptoms and mechanisms they can, by and large, be generally diagnosed and treated with reasonable success.

Functional or biogenetic disorders may be, for purposes of consideration, separated into two groups: The emotional reactions, and the substitution reactions. The formal classification of the various disorders will not be considered here as they may be found in any good textbook on psychiatry.⁹

Emotion may be looked upon as the feeling one experiences and its expression. Mood and affect are terms generally used synonymously. Sometimes mood is used referring to the feelings and affect to the expression of the mood. Affect is also used in the sense of the feeling tone of the idea or situation. Elation, depression, and fear with their variations are the usual affects. The most common emotional mechanisms are elation, depression, anxiety, anger, and fault-finding states. They not only concern the feelings but also the reactions of the personality which involve feeling, action, and thinking. These are not different from natural expression of feelings except when they become exaggerated or pathological.

The elated mechanism shows the patient not only to be feeling good, but he feels over-good and out of proportion to the situation: his eyes are brighter, he speaks more, he gestures more, his field of interest becomes enlarged and he takes in more; he functions easily, his appetite is good, his gastrointestinal tract functions¹⁰ satisfactorily, he is alert and quick and he coordinates well; his face is flushed and he has a physiological feeling of warmth and a psychological feeling of well-being with nothing impossible. The step from high spirits, vivaciousness, and exhilaration to a pathological emotional reaction is short and may be overreached easily.

In the depressed reaction the opposite clinical picture is seen: the patient is blue and sad, or says he has no feeling; he is not as alert as usual and is quiet and talks and moves about less; his field of interest is narrowed and he is slow in both speech and action. His appetite is not good, he complains of fullness in the stomach and abdomen and constipation; headache and tightness are not unusual; he appears pale, does not feel well, and tires easily. He has lost his "pep"; he feels inadequate, uncertain and pessimistic, and even self-depreciatory. Suicidal attempts are frequent.

In the anxiety reaction the patient is anxious, worried, and generally restless. There is a tendency to talk and to unload with harping, and there is a narrowing of interests. Other patients may talk less and appear stunned. Here too we find loss of appetite, constipation, dryness of the skin and mucous membranes, and uncomfortable feelings in the region of the heart and even slight acceleration of the pulse. There may be complaints in the region of any organs of the body.

In the fault-finding reaction the patient appears uncomfortable and dissatisfied. There is the appearance of uncomfortable emotional tension with talkativeness and tendency to unload and have it out. There is a diffusion of interest in that everything and anything or anybody in the environment will be harped upon and complained of. The patient is generally out of sorts.

The anger reaction is a shorter and episodic reaction. The physiological and psychological picture of the angry man is familiar to all. The psychopathological interest is in the recurrence of these episodes without adequate cause and the lack of control manifested.

In the substitution reaction is found split-

ting of the psyche. Complexes or groups of ideas with their affects or feelings are separated off from the rest of the psyche. They appear in one way or another as symptoms. These complexes may appear in the form of hallucinations, paranoid and fantastic delusions, obsessions, compulsions, and hypochondriasis. Scattered and stilted talk may be present. Apathy, exaltation in contradistinction to a feeling of exhilaration of the emotional reaction, and aggressiveness take the place of normal or more salutary reactions. The symptoms may be formulated into types or reactions.

The schizophrenic or schizoid reaction type or mechanism is characterized by a change in attitude toward reality and the problems of responsibilities of life. There is a loss of interest, an impaired emotional reaction, absorption of interest in the inner life, day-dreaming and ruminating, and finally hallucinations, delusions, changes in stream of talk, with reactions of apathy, exaltation, aggression, stupor, and in specific and direct relation to their delusions. Strange and queer behavior is common. The early stages of this reaction are often not recognized until some bizarre conduct has developed or until the physician after dealing with the hypochondriacal complaints comes to see them as delusions. Not all of these cases progress rapidly nor do they all develop into severe psychoses and states of deterioration. It is advisable to keep in mind that there is always present the possibility of a severe reaction in the form of a sudden acute episode. On the other hand many of these cases live outside of hospitals as limited but productive individuals. In milder and acute cases there are gastrointestinal complaints with spastic constipation.

The paranoid reaction is seen frequently and may vary in degree from suspiciousness to paranoid or expansive delusions of ability and authority. Paranoid patients may have indefinite feelings of changes in people's attitude toward them or in their bodies. The manner may be one of condescension or superiority. Advice is sought but seldom followed and is generally viewed with suspicion. These patients consult physicians for their change of feelings and are nervous and letdown.

The hypochondriacal reaction presents many bodily complaints which are elaborated beyond the usual somatic syndromes met with. The usual physical signs of somatic disease are absent and frequent

examinations tend to fix and elaborate the complaints. Peculiar eating habits are often present. Close study of the complaints show certain bizarre features. There is also found a certain lack of affect and reality to the total picture presented. The case may progress to a well defined and severe psychosis but this is not the rule. These patients consult many physicians and quacks and take up religious, nature, and other cures.

The psychasthenic reaction presents obsessive, compulsive and somatic symptoms and feelings of weakness, but always in a setting of emotional or affective inadequacy. Feelings of uncertainty and unreality are common.

Hysterical reactions and anxiety neuroses are here considered separately from the psychasthenic reaction. Hysterical reactions are manifold in their manifestations and are familiar to all. Fugues, somnambulistic states, dreams or delirious states and conversion symptoms with their somatic manifestations are the most common. For the present consideration the dreamlike or delirious states and the conversion phenomena are the most important.

Delirium in the sense of an organic reaction is conditioned upon an inability to apprehend, and clinically the post-delirious state presents a temporal or time defect in memory. The hysterical delirium is conditioned upon a state of complex disassociation and the post-delirious state presents a topical or subject defect in memory—rarely is time involved. The trend in the former is scattered and has to do with habitual experience. In the latter the trend has to do with an unpleasant or painful subject or situation. Accompanying the conversion somatic symptoms are the typical hysterical stigmata. The somatic symptoms are not anatomically circumscribed; either they are too limited or too diffuse to conform with the structural relation of the body. The disassociated complex in hysteria is complete with its affect which is not bizarre and appears more natural. In schizophrenia the whole picture is peculiar and unreal. It is the conversion symptoms of the internal organs, heart, and gastrointestinal tract, and so on, which especially give physicians trouble. Many of these patients undergo much unnecessary treatment and many unnecessary operations. It is only by a careful study of the history of the patient and his personality that the case becomes clear.

The anxiety neurotic type of reaction is generally looked upon as one of the psychoneurotic group to which hysteria belongs. It seems best to discuss it separately. The clinical picture is one of fear of something impending, losing the mind, tumors or other somatic diseases; of feelings of depression, irritability and inability to concentrate or undertake things. There are no parts of the body exempt from representation in the somatic clinical picture. Palpitation, precordial pain, shortness of breath, abdominal distension, flatulence, constipation and diarrhea, spots before eyes, ringing in ears, tremors, perspiration, frequent urination, dizziness, and paresthesias are some of the common complaints. The patients' cases are often diagnosed as having somatic disorders or as "cardiac neuroses," and so on. In their less apprehensive states with the greater emphasis on the somatic symptoms they present problems to the practitioner which are not easily solved. In the end a careful study has to be made of the history and personality of the patient before an accurate diagnosis can be arrived at.

In considering the syndromes presented it is important that the physician should bear in mind the great variability of the symptoms; the possibility of atypical clinical pictures; and also that symptoms of more than one syndrome may be present at the same time and produce a mixed picture—this latter is especially true of the occurrence of organic and functional syndromes; and that the personality of the patient also plays a great part in modifying the clinical picture.

The purpose of this paper has been to call the attention of the general practitioner to some of the formulations of psychiatric medicine which may be helpful in the study of his cases. Too often psychiatric problems are observed, discussed, and managed in a superficial hit-and-miss fashion. Psychiatry like metabolism and immunity, among other fields of medicine, has developed a terminology of its own. This does not mean that it cannot be readily grasped by those in other branches of medicine, that it is loosely conceived or vaguely formulated, or that it cannot be discussed in simple every-day language. It is true that there are many questions we cannot answer; the same may be said of immunity. It is equally true that there is a large body of psychiatric knowledge that is readily available and practically helpful

for those who will take the time to look into it and to study their cases in the light of the knowledge available.

Psychiatry has made a great contribution to medicine. It was the first of the medical disciplines to accept, to put to the test, and to establish on a practical basis the principle of biogenesis as applied to medicine. If the physician will apply this principle to his nervous and mental cases as the author has pointed out elsewhere⁸ his facility in understanding his patients will be materially increased. The fact that man does not function as a summation of

parts but as an integrated whole¹¹ is worthy of meditation.

This presentation has been brief and limited to some of the more important formulated reaction types of psychiatric medicine. Etiology, psychological mechanisms of development, and treatment have not been discussed because of the limited time available.

To those who may be interested in following up this discussion, the studies of Cannon,¹² Hoch,¹³ Bleuler,¹⁴ Zilboorg,¹⁵ and Jamieson and Wall,¹⁶ are especially recommended. 121 WESTCHESTER AVENUE

CHIROPRACTORS BROUGHT TO JUSTICE

A drive against chiropractic schools is being made by the State Department of Education, on the charge of issuing degrees without sanction from the Legislature or the regents, in violation of the law. The officials of one school have pleaded guilty and are under suspended sentence, and the cases of two other schools will come up shortly.

In addition to prosecuting the schools an active campaign is now under way against individual practicing chiropractors, it is said. Chiropractors, of course, are not licensed in New York and the Court of Appeals has held that the practice of Chiropractic is the practice of medicine and that those who engage in it as the practice of medicine do so illegally. The offense is a misdemeanor and carries with it the penalties of one year in jail or not more than \$500 fine, or both. Individual practitioners at the rate of ten or twelve per month are now being arrested and brought to trial through the work of

the bureau headed by Sol Ullman, Assistant Attorney General in charge of the investigation of illegal practice of medicine and dentistry.

The decision of City Judge Jacob A. Bernstein of Mount Vernon upholding the constitutionality of the law has attracted wide notice and was cited in a recent article in THE NEW YORK STATE JOURNAL OF MEDICINE.

THE DOCTOR'S PRESTIGE

Dr. George W. Hartmann, of Pennsylvania State College, interviewed 450 persons in various walks of life and asked how they rated different occupations in the matter of prestige. This is how he found them to stand in public esteem: First, physician, then United States Senator, professor, lawyer, civil engineer, dentist, clergyman, high-school teacher, factory manager, merchant, salesman, nurse, actor, mail carrier, garage mechanic, tailor, bricklayer, baker, policeman, plumber, miner, barber, cook and fisherman.

THE PROBLEM OF ACUTE APPENDICITIS IN NEW YORK CITY

SHEPARD KRECII, M.D.

NEW YORK CITY

Introduction

Vast quantities of words have been written and spoken about acute appendicitis. We have had it paraded before us in medical literature and discussed repeatedly at medical meetings. It has become such a common part of our professional diet that we have lost our taste for it. We shrug our shoulders and accept it as an inevitable evil. We wonder what more can possibly be said about it, and we go to medical meetings with a feeling of resentment and boredom that we are asked to listen to just another paper on appendicitis. But when we hear that the operative mortality of acute appendicitis in fourteen representative New York hospitals was 7 per cent in 1921 and only one-tenth of one per cent less in 1931, we may agree that the time has not yet come to dismiss the subject. On the contrary, it is ripe for a united and constructive effort on the part of the medical profession of New York toward correcting this condition.

Some time before his death, Dr. Linsly Williams, Director of the New York Academy of Medicine, suggested that a survey on acute appendicitis, similar to those that have been conducted in other cities, should be undertaken. It is with deference to his wishes and respect to his memory that I offer you this survey.

General Consideration of Incidence and Mortality of Appendicitis

In 1927 Dr. J. V. De Porte, Director of the Division of Vital Statistics in the New York State Department of Health, undertook a "Sickness Survey" of rural New York. His findings are based on weekly reports received over a period of one year from 107 physicians in 33 counties serving a total population of about 100,000. Each physician agreed to report only new cases as they were seen for the first time. No subsequent visits were reported. It is an interesting side-light on the rural incidence of certain diseases:

Measles	1201
Bright's Disease	1134
Appendicitis	966
Gonorrhea and Syphilis.....	908
Chicken-pox and Whooping Cough.....	882
Scarlet Fever and Pneumonia.....	566
Diabetes	505
Cancer (all forms).....	464

The report does not state how many of these cases of appendicitis were of the chronic type, or how many came to operation. But at least it shows that the diagnosis is made with astonishing frequency, and is a fair indication of the prevalence of appendicitis.

The concentrated attention of the Medical Profession, the Department of Health, and the laity in New York City has been directed for many years against the contagious diseases. The result has been a very marked reduction in the number of deaths from these causes. The Health Department figures show that in 1920 there were 2,876 deaths from the following six contagious diseases: Measles, Whooping-cough, Scarlet-fever, Diphtheria, Typhoid-fever, and Epidemic Meningitis. In 1933 there were 629 deaths from these same diseases. This represents a reduction of 78 per cent. The number of deaths from appendicitis, however, has shown a gradual rise during the same period from 792 to 1,149, an increase of 45 per cent. (See Chart I.)

In 1930, 1931, and 1932—the period covered by the Maternal Mortality Survey conducted by the New York Academy of Medicine) there were 2,041 deaths from puerperal causes registered with the New York City Department of Health. In the same period there were 3,333 deaths from appendicitis.

The reduction in the mortality (deaths per 100,000 of population) of Diphtheria and Tuberculosis is compared with the rise in the mortality of Appendicitis. (See Chart II.) Diphtheria and Tuberculosis have been the objects of a well-organized attack on the part of the medical profession, health officials, and the

Read before the New York Academy of Medicine, November 8, 1934. By special arrangement this article appears also in the Bulletin of the New York Academy of Medicine for March, 1934

CHART I.—Numbers of deaths in Greater New York City from six contagious diseases, and from appendicitis, 1920-33.

laity. Appendicitis has not. These figures are taken from the actual death certificates, which implies an accuracy of diagnosis which is not without a factor of human error. However, the general trend is obvious, and lacking any other better method of obtaining this information, they must do for the present. The fact remains that appendicitis is a common condition and its mortality in New York City is too high.

The Survey

The rest of this paper will be devoted to an analysis of 4,542 cases of acute appendicitis, prepared from a personal study of each individual chart in the record rooms of fourteen hospitals in Manhattan. An attempt has been made to draw a ten-year comparison between the years 1921 and 1931. In a few instances hospital records were not available for 1921, so the nearest subsequent year was taken in order to carry out the comparison. Unfortunately there has not been time to bring this record up through 1933, as the work was started in 1932 and only recently finished. I wish to thank the directors of surgery, the superintendents and the record room employees of these hospitals for their cordial reception, and

CHART II.—Comparative mortality per 100,000 population of appendicitis, diphtheria, and pulmonary tuberculosis in New York City from 1921 to 1933. The New York City Health Department bases its rate of diphtheria on the number of deaths per 100,000 under 15 years of age.

to say that in no instance was any diplomatic difficulty encountered. The following hospitals cooperated in this work: Bellevue, Beekman Street, Broad Street, French, Harlem, Lenox Hill, Mt. Sinai, New York, Polyclinic, Post-Graduate,

CHART IV.—Comparative mortality as to age in 1921 and 1931.

CHART V.—Numbers of deaths from all forms of appendicitis as based on figures supplied by the Health Departments of the City and State of New York.

Presbyterian, Roosevelt, St. Luke's and St. Vincent's. This is obviously a representative list of the Grade A hospitals, and the result in these hospitals might fairly be expected to be somewhat above the average for the whole city.

Only those cases of acute appendicitis in which the diagnosis was certain beyond any reasonable doubt have been included. Many cases were rejected in which the operative description or pathological findings were unconvincing. No cases of so-called chronic or sub-acute appendicitis were included, nor were any of those which were operated on during the interval between attacks. In 1921 2,208 cases were operated upon in these 14 hospitals. In 1931, 2,334. In some of the following statistical charts the two years have been combined because the figures of either year were of no particular significance from a comparative standpoint.

Age Incidence and Age Mortality

There was a variation of less than 1 per cent throughout in the age incidence in the two years, and therefore they are charted as one. In 29 cases the age was not recorded on the charts. There is nothing particularly interesting here except further evidence that acute appendicitis is primarily a condition of youth and young adult life, nearly 56 per cent of all cases occurring in the second and third decades. (See Chart III.)

The comparative mortality according to age, on the other hand, is of some interest, because it shows in 1931 a marked increase over 1921 in the older age groups. This might be accounted for on the basis that people over 50 have been unable to throw off the ill effects of unemployment and economic stress as well as the younger groups have, and have suffered an attack of appendicitis in a condition of comparatively greater lowered resistance. (See Chart IV.)

Sex Incidence and Sex Mortality

The incidence according to sex checks pretty well with other authors—68 per cent males—34 per cent females. The mortality according to sex is a different story. The Health Department figures for the City in 1921 show 495 deaths among men and 329 among women, and in 1931, 682 among men and 475 among women. In the rest of the State the same relative picture holds true. This chart gives us a

good picture of the increase in the number of deaths in both sexes during the 10-year period in both City and State. The actual mortality among men was slightly higher than that among women (7.2 per cent and 6.8 per cent in the hospitals studied. (See Chart V.)

Seasonal Variation

The question of seasonal variation has been discussed by others. This chart is based on only 2,672 cases. It is difficult to explain the marked rise during the month of March. Most of us, however, have probably observed in our hospital work the later rise that occurs during the summer months. The curve seems to follow somewhat the curve of exacerbation of peptic ulcer. There are some who might offer it as evidence in favor of the bacterial theory of the etiology of ulcer. At least we are all familiar with the apparent clinical association that exists between symptoms of peptic ulcer and a pathological appendix. Seasonal variation is a matter which would bear further study. (See Chart VI.)

Previous Attacks

The question of previous similar attacks was studied with the hope that it might cast some light on the attitude of mind of the public. If it could be demonstrated that in 1931 more patients sought admission in hospitals during their first attack of abdominal pain than was the case in 1921, it might be favorably construed as a step forward. Here we are confronted with a discouraging surprise. In 1921 40 per cent of the hospital charts contained no information about previous attacks, and in 1931 nearly 45 per cent.

Discarding all charts that contained no information, we find that in 1931 fewer patients were admitted during their first attacks than in 1921—46.4 per cent as against 48.7 per cent. This can hardly be construed as evidence that the public has become more "appendix minded."

Cathartics

I hesitate to present any figures on cathartics because of a woeful lack of information. In 1921 69 per cent of the hospital charts were completely lacking in any mention of catharsis, and in 1931, 63 per cent. Again in 1921 such information as was given was incomplete in 20 per cent of the charts, and in 1931 16 per

cent. We are, therefore, reduced to such a small number of cases in which this information was complete—230 in 1921 and 468 in 1931—that any conclusions would be of little value. No attempt was made to compare the mortality in the "cathartic patients" with that in the "non-cathartic" group because of this incomplete information. Nor was it possible to answer many other important questions in this category, such as: Where lay the responsibility for prescribing cathartics? What kinds predominated? What was the effect on the symptoms, and what apparent relation did catharsis bear to the pathology found at operation and the subsequent course of the illness?

There are some who still feel that too much emphasis has been laid on the whole question of catharsis. The anti-cathartic campaign that has been waged in Philadelphia is now familiar to all. Several years ago the County Medical Society there sent out 300,000 stickers to 3,813 physicians to be attached to their monthly bills. The sticker read:

"Warning—In the presence of abdominal pain never give a laxative. Give nothing by mouth. Apply ice-cap or hot water-bottle. Call your family physician. Abdominal pain which lasts over six hours is usually serious. This warning is published by the Philadelphia County Medical Society and endorsed by the Department of Public Health."

Further propaganda was launched through the press, radio, retail drug stores, and in the class-rooms of the public schools. Bower believes that the creditable reduction in the mortality of acute appendicitis in Philadelphia has been due in some measure to this anti-cathartic cam-

Presbyterian, Roosevelt, St. Luke's and St. Vincent's. This is obviously a representative list of the Grade A hospitals, and the result in these hospitals might fairly be expected to be somewhat above the average for the whole city.

Only those cases of acute appendicitis in which the diagnosis was certain beyond any reasonable doubt have been included. Many cases were rejected in which the operative description or pathological findings were unconvincing. No cases of so-called chronic or sub-acute appendicitis were included, nor were any of those which were operated on during the interval between attacks. In 1921 2,208 cases were operated upon in these 14 hospitals. In 1931, 2,334. In some of the following statistical charts the two years have been combined because the figures of either year were of no particular significance from a comparative standpoint.

Age Incidence and Age Mortality

There was a variation of less than 1 per cent throughout in the age incidence in the two years, and therefore they are charted as one. In 29 cases the age was not recorded on the charts. There is nothing particularly interesting here except further evidence that acute appendicitis is primarily a condition of youth and young adult life, nearly 56 per cent of all cases occurring in the second and third decades. (See Chart III.)

The comparative mortality according to age, on the other hand, is of some interest, because it shows in 1931 a marked increase over 1921 in the older age groups. This might be accounted for on the basis that people over 50 have been unable to throw off the ill effects of unemployment and economic stress as well as the younger groups have, and have suffered an attack of appendicitis in a condition of comparatively greater lowered resistance. (See Chart IV.)

Sex Incidence and Sex Mortality

The incidence according to sex checks pretty well with other authors—68 per cent males—34 per cent females. The mortality according to sex is a different story. The Health Department figures for the City in 1921 show 495 deaths among men and 329 among women, and in 1931, 682 among men and 475 among women. In the rest of the State the same relative picture holds true. This chart gives us a

appendicitis. If it were possible to have complete information and to devote more time to a painstaking study, we would also find here the true evidence of the skill and judgment of the individual surgeon. The removal of an early acute appendix is ordinarily a fairly simple procedure. But there is not a single surgeon here tonight who has not had his technical ability, patience, and judgment taxed to their limits by the difficult appendix that is complicated by an abscess or peritonitis. It is only through these trying and bitter experiences that we learn to develop a humble and wholesome respect for this small but dynamic organ.

In studying the individual charts from the pathological angle the difficulty of interpreting the operative findings of others was impressive. But an honest effort has been made to do this with an open mind, and to classify each case as fairly and accurately as possible. I admit a considerable factor of human error, but at least it is a constant one, due entirely to the interpretations of a single individual.

I have followed the pathological classification in use at the Presbyterian and a few other hospitals. There are 5 groups: 1. Acute appendicitis (uncomplicated), 2. Acute appendicitis with acute local peritonitis, 3. Acute appendicitis with peritoneal abscess, 4. Acute appendicitis with acute diffuse peritonitis, 5. Acute appendicitis with progressive fibrino purulent peritonitis. (See Chart X.)

1 Acute Appendicitis (Uncomplicated)
The first group is simple and clear cut. The pathological picture may vary from the appendix which shows injection of the serosal surface, edema of its coats, invasion by polymorphonuclear leukocytes and erosion of the mucosa, to one of advanced gangrene. But only if the process has remained entirely limited to the appendix has the case been classified in this group. The presence of clear peritoneal fluid has not been interpreted per se as peritonitis. As might be expected, the great majority falls into this group.

2 Acute Appendicitis with Acute Localized Peritonitis
Here the pathological process has escaped beyond the confines of the appendix itself. We find the deposition of plaques of fibrin about the appendix, cecum, and possibly neighboring intestinal loops. The omentum will probably be involved in the inflammatory

process in its ever watchful role of guardian of the peritoneal cavity. The wall of the cecum and nearest loops of small intestine will be injected and somewhat dilated, and there may be some clear or turbid or even frankly purulent fluid in the vicinity.

3 Acute Appendicitis with Peritoneal Abscess
This classification is simple if we merely bear in mind just what an abscess is. Here there will be a circumscribed collection of pus, usually of foul odor, maybe a few drops or maybe many ounces. It will be completely walled off from the rest of the peritoneal cavity. The appendix will probably be found in the abscess cavity or one of its walls. These walls will be composed of different structures depending on the location of the abscess. They are the result of a local peritonitis. They are the brick and mortar produced by the peritoneum and omentum.

4 Acute Appendicitis with Acute Diffuse Peritonitis
In attempting to allocate cases to this 4th group I have tried to bear in mind constantly the definition made by Dr. Joseph Blake in 1903, and recently revived by Potter: "By diffuse peritonitis I mean an established progressive inflammation without definite limitations, evidenced by extensive redness of the peritoneum, a definite inflammatory exudate, a tendency to general involvement and intestinal paralysis."

There are some who prefer the term "spreading peritonitis." Is not the whole process of acute appendicitis from its onset a constantly spreading and

CHART X—Incidence of pathological types

full of pus, the dilated paralyzed intestines, and feel the failing pulse of the patient who has spent several days with an icebag on his right lower quadrant. One does not learn by listening to words. Our strongest impressions are created by actual observations. What really counts is the practical and tragic experience of seeing these patients on the edge of the grave.

950 PARK AVENUE

Discussion

DR. WILLIAM W. HERRICK (New York City): Dr. Krech deserves a great deal of credit for the completion and for the clear and convincing presentation of a very important task. Faced with the fact that the mortality from acute appendicitis in our more representative hospitals is 7 per cent, we must realize that the mortality in the community at large is probably higher. In appendicitis we have a disease which, with ordinary diagnostic and surgical skill, is presumably remediable, and yet appendicitis has a mortality quite as high as that of enteric fever, a disease for which we have no remedy. This state of affairs, indeed, deserves a searching of method on the part of those who teach medicine, of those who practice medicine and of those who are practiced upon.

I am sure that as a student and as an interne, I had no adequate instruction in the dangers of abdominal pain or in the care essential in its management. Teachers of medicine are but human. We tend often unconsciously to suppress our errors of diagnosis and of operative judgment and technic, when those errors should be exploited for the benefit of the student. In every senior medical course and in every hospital particular emphasis should be laid upon mistakes in diagnosis and upon their clinical and the pathological aftermath.

Another factor in the mortality of appendicitis is the common practice of making too few house calls. It was the practice of an earlier day to see the patient with any acute condition daily, or perhaps twice a day. Now with the economic pressure, the patient does not crave the medical attention that he used to, neither does the physician wish to force upon the hard-pressed patient services which he thinks may not be necessary. The physician is inclined to leave some of the responsibility on the patient, to say: "If you are not all right tomorrow, let me know and I will come again." In the question of an acute abdominal disorder, such an attitude may mean disaster. A way to avoid this is to enforce early hospitalization of cases of the acute abdomen which cannot be provided with adequate facilities for care at home, a

care which may include hourly observation, with appropriate laboratory procedures.

Another source of danger is in our own processes of reasoning. These brave many possibilities of error. The method of logic which we so often must apply in diagnosis, "per exclusionem in ordine," is so beset by error that frequently the single mind endeavoring to make a diagnosis goes astray. I believe it was Sydenham who said that there are times when one's faculties are holden from him; that is, when the fine coordination of brain and sense and hand is not operative at an efficient pitch and, when through fatigue or what you will, mistakes of observation and of interpretation and of judgment creep in.

In diagnosis of abdominal pains such a situation can be shunned by the consultation. The surgeon and the medical man should share the responsibility for the diagnosis of the acute abdomen.

On the side of the laity, I think there has been an increasing, shall I say, disrespect for appendicitis. The average citizen considers it a fairly simple, straightforward matter, one that can be remedied by almost any surgeon. He is a little lax in sending for his physician and in the use of cathartics. Some attempt to re-educate the laity along these lines seems desirable.

Again the public should recognize one point of utmost importance, namely, that an appendectomy, while it may be a very simple operation, can be one of the most complex and difficult procedures, demanding all the skill and resource of the surgeon. Appendectomy should be entrusted only to surgeons thoroughly competent. A rule enforced by some appropriate organization should provide that major surgery of this type be done only by those thoroughly qualified by training and experience. I would like to sum up the medical point of view by saying that there should be more adequate instruction in the subject of abdominal pain, and in the results of mistakes in its diagnosis and treatment. More frequent visits should be made in the home when the acute abdomen is under consideration. Each case of abdominal pain should have the benefit of both the medical and the surgical consultation. Early hospitalization of cases of this kind should be enforced, the laity instructed in the dangers of acute appendicitis and in the necessity of placing its management in the most competent of surgical hands.

DR. JOHN A. HARTWELL (New York City): Mr. President, Dr. Krech, Dr. Parman, Fellow Guests of the Academy: I am afraid that I shall speak more as one who is retired from the practice of surgery than from an active surgeon's viewpoint. First, I wish to comment upon the fact that the Academy possibly felt a little too chastened

over a recent experience that was connected with a similar study to this called the Study on Maternal Mortality. There were certain events connected with that which left an undying impression upon the minds of those of us who took part in it.

I rather regret that we did not advise Dr. Krech to entitle his paper, "The Problem of Acute Appendicitis in New York City—An Outgrowth of the Study on Maternal Mortality, A Challenge by the Obstetricians to the Physicians and the Surgeons," and then I think we would have had this hall filled; particularly if we had released this paper to the press, and it had appeared on the front page of all the papers this morning as: "One out of every fourteen cases of acute appendicitis dies. What are the surgeons going to do about it?"—or something of that sort.

We were severely criticized for the maternal mortality report because it did get out. It was not intentionally that this was done, but a good many of us feel that it has been a good thing because it did attract attention, and also it aroused the obstetrical portion of the profession to the fact that something should be done about it.

It is incumbent upon the Academy to see that this work yields results, for when 1,100 persons die in this city of appendicitis every year, it is a matter of major importance and becomes pretty nearly a public health problem. And when we find, as we do, that the death rate is constantly rising from it in spite of the fact that patients have come earlier in 1931 than they did in 1921, it shows we are not going to conquer the problem entirely by getting all the people to come to the surgeons earlier. There is another element in it. And when we realize that when one is past the age of fifty, though it is rare that he has appendicitis, his chances of living are only about three in four, it is a very serious problem.

Too, as Dr. Herrick pointed out, it should be remembered that these statistics are taken from fourteen of the graded A hospitals and probably represent the highest type of treatment.

We don't know what the minimum death rate of acute appendicitis ought to be, but we do know that 7 per cent is too high, just as we know that the maternal mortality rate was too high. Since that report was published, definite steps have been taken to see that an improvement has been made in which the Department of Health is taking a part by having appointed an Advisory Obstetrical Council. This council is now engaged in studying the recommendations contained in the Academy report and endeavoring to put them into practice.

Another factor that Dr. Krech brought out is that the records, even in our best hospitals, are not as good as they should be. We do

not like to emphasize that because these hospitals were very courteous and co-operative in giving every opportunity to Dr. Krech to study their records, but at the same time they like to know where they may profit and it is our experience that the hospitals eagerly accept any knowledge that will be of benefit.

It was very apparent that the uncomplicated pathological process ran parallel in each instance to the earliness with which the patient came to the operating room. Early, the disease is a comparatively simple problem in the majority of instances, but even here there is enough trouble to cause a very considerable death rate.

The total number of cases was about 4,500 in the two years, a little over 2,000 in each year. That is a goodly number to make a careful study of.

What can we do about it? How can we proceed? We obviously can't proceed unless we can arouse interest. In the case of maternal mortality, we have to acknowledge, frankly, the profession was driven by the laity. The report came out and it was largely instigated by lay organizations and the profession was aroused only when the situation was emphatically called to their attention.

If an undesirable condition exists in appendicitis, it probably exists in a great many other surgical conditions. If we are satisfied with any bad condition that exists, we don't get any further. There are apparently many unnecessary deaths from appendicitis and it is certainly the duty of the profession to see that those unnecessary deaths do not occur.

Dr. Krech has made one specific suggestion as to how we should proceed; namely, that we ask all the hospitals to co-operate in an intensive study of the condition of appendicitis, keep their records fully and have those records analyzed by an impartial and carefully selected committee and reported upon to see exactly where there are factors that have been responsible for death that might be eliminated.

There are, somewhere along the line, elements that we may get rid of if we know all the facts and everybody's mind is intent upon it, and when there are 1,100 persons each year dying in this city of this disease and when the mortality in the acute condition rises as high as 7 per cent, we certainly should take steps to see that improvement occurs.

How shall we proceed to do this? Well, I suggest, Mr. President, that since the Academy has introduced the subject—and it really has been an outgrowth of the report on maternal mortality—that the Academy take upon itself the responsibility, through one of its committees, to launch a study of this disease and possibly other surgical conditions along the same intensive lines that

the study of maternal mortality took, and learn wherein we can improve the situation. It is not worth while to do the hard work that Dr. Krech has done over two years, possibly longer, with the co-operation of fourteen hospitals and then have the paper simply filed away and forgotten. Such a work is only justified if it lead to some effort to improve the conditions that it describes, and I trust that the Academy will seriously recognize its responsibility and lead towards setting up a procedure such as Dr. Krech describes in the paper for making the intensive study that is necessary to be made.

For example, why did some 30 to 40 per cent of these patients get to the operating room only on the third and fourth day? Was it because they didn't inform anybody that they were ill? Was it because of the difficulties, the inherent difficulties of diagnosis, which is perfectly possible? Was it because someone in the line was careless, didn't take trouble enough to find out the situation? What were the factors that led to delay?

Again, what were the factors that caused the deaths in the cases where there was a local abscess, a condition that, as Dr. Krech pointed out, ordinarily is fairly easily dealt with, but in some instances may tax the best surgeon's ability? A complete analysis of that sort should lead to an improvement in the situation, and unless we accept that responsibility, I do not feel that we have done our full duty.

I wish to thank Dr. Krech in the name of the Academy for having undertaken this work and pushed it forward to this extent and made the suggestion that we go on with it.

DR. THOMAS PARRAN, JR. (Albany): Mr. President, Dr. Krech, Fellow Members of the Academy: In the very cryptic statement of Dr. Krech as to the reasons why he undertook this study, I think very few of us have appreciated the enormous work involved. When we consider the task which he undertook some three years ago of analyzing the raw data from these fourteen hospitals, of classifying and transcribing and interpreting these data, it is very difficult to appreciate the extent of the contribution he has made.

Many of us are familiar with statistical studies carried out by organizations of one sort or another, but it is quite rare, I think, to find a physician in practice, a surgeon, who has the time, the inclination, the ability and the energy to lift his eyes from the scalpel to the community problem with which he is dealing, and attempt to answer some questions in relation to it. This Dr. Krech has done with appendicitis in this city.

I think none of us should mistake the fact that this is a real problem, that appendicitis in its influence upon the health of the community is a very significant factor.

Reference has been made already to the discussions, the acrimonious discussions, I might even say, concerning maternal mortality in this city, and yet what are the relative losses as between deaths from puerperal causes and appendicitis? Last year in New York City, there were 665 deaths from all puerperal causes and 1,149 from appendicitis.

Let's compare a few more causes of death. Measles in the same year, 213; whooping cough, 129; scarlet fever, 59; diphtheria, 86; typhoid fever, 70; while appendicitis accounted for 1,150 deaths in this city. More than that, the great bulk of these deaths occurred in the younger and, therefore, the most productive age group, which lends even greater significance to the deaths from this cause. Seventy per cent of the deaths occurred under forty years of age.

Dr. Krech, it seems to me, was very modest in saying that his was not a scientific paper. Perhaps it was not in the sense that a surgeon considers a paper to be scientific, but actually it is a very scientific contribution. It is the first broad-scale study of the appendicitis problem in this city and as such, I think is a distinct scientific contribution, and one to which I hope the widest publicity will be given. I hope the facts which have been ascertained will be disseminated widely among the public and among the profession.

The truth of the matter is that we are making no progress whatever in regard to this appendicitis problem. We are familiar with progress which has been made in reference to many other diseases and conditions, and yet in regard to this very important disease, we are making no progress whatever. We are faced with a constantly increasing death rate.

Dr. Krech was very soft in some of his criticisms, it seems to me. He referred rather casually to the value of vital statistics data. Well, when he discussed more in detail the value of the hospital data, I think he proved that neither one of them is very good. The value of any vital statistics records or hospital records does not go beyond the accuracy with which the original entries are made. Many physicians, I know, place very little value on the data gotten out by health departments, but remember that the lack of value is due to the lack of accuracy of physicians in recording definitely the cause of death. As we look over these data, we would assume that nobody outside of the ward room dies of syphilis. We would assume that nobody except the charity patient ever died of alcoholism, simply because doctors hesitate to put down for their private patients these two and other causes of death.

When we come to study the hospital records in these 14 hospitals, time after time, Dr. Krech shows the data are lacking for 60 or 70 per cent of the cases. In other words,

a large proportion of the records mean nothing. He has been very charitable in not pointing out which of those hospitals are the greatest offenders. I think a very significant service can be rendered to the staffs of those hospitals, a service which I hope they will ask Dr. Krech to render to them, by pointing out how they stand in reference to the other hospitals concerned. I hope some representatives of the surgical staffs of the hospitals are here tonight and that you will not lose this opportunity to find out from Dr. Krech wherein your records are lacking in comparison with these other institutions.

One of the discussors has said that this is a public health problem. Quite true, and yet I am very much gratified that a recommendation is not made primarily for some action by a health department. It seems to me that in this instance there is an opportunity for the hospitals concerned, the surgeons, concerned, under the aegis of such an organization as this to make a thoroughgoing study, using uniform records to ascertain some of the unknown factors in this situation.

We do not know why it is that the male is 50 per cent more susceptible to appendicitis than the female, a very important question it seems to me, to which we should find an answer. We do not know why the number of cases and the number of deaths in September double those in December and January. What are the factors which contribute to this selective sex incidence and the selective seasonal incidence of appendicitis? Broad epidemiological studies are obviously needed on those two facts which may throw some light on prevention.

I think that all of us recognize if appendicitis is recognized early, promptly operated upon, the mortality is about one seventh as shown by these figures, of the average mortality. Here there were 1,149 deaths last year in this city. Certainly that should be reduced to 100 or 200, if the proper effort is brought to bear upon it.

It seems to me that here is another great opportunity for service on the part of this organization to study thoroughly this problem. A splendid start has been made. Much more data are needed and can be assembled, the results of which, I am sure, will mean lives saved, deaths reduced from this cause in this city.

Dr. McCreery (New York City). I have been rather on the side lines, perhaps, in this study of Dr. Krech's. I have gone over with him his books of records from the different hospitals, his master charts, and have discussed with him at considerable length his findings and thoughts on his report. I don't think that the Society quite realizes the amount of time, the amount of careful thought that has been put into this study.

There is one point which Dr. Herrick

brought out which I think needs emphasis and that is the question of the instruction of the undergraduate and perhaps to a somewhat lesser extent of the interne in the subject of the acute abdomen and of the acute appendix. Dr. Krech has shown tonight that the acute appendix is one of the major causes of death in the City of New York in the course of a year, and yet as we look over the courses of study in the Grade A medical schools, we are forced to realize that through the increased demands for time on the part of all departments, the amount of time that can be given to the basic subjects—which perhaps those of us who are in general practice feel are of more importance—is being cut down. In one school the amount of time which has been devoted to the subject of appendicitis has been cut down 80 per cent in the last few years.

I know it is hard to squeeze a few more hours into the curriculum, but I do feel that if in the future it will be possible to give more time to these acute conditions, the end results as shown in mortality and morbidity figures, will be very much improved.

Dr. C. W. Crampton (New York City). Mr. President, I have been very much instructed by the speakers this evening and there have been many points which seemed to me of considerable importance, one of which is the point mentioned by Dr. Hurtwell. But there is an apathy in the medical profession with reference to this point of appendicitis. I think twenty years ago the subject was brought out to a far greater audience and twenty years ago a great deal of the discussion was of an acrimonious nature by medical men against the surgeon and they were answered in kind. I recall, I think many of you will recall, many such sessions.

I should like very much to hear if any of the speakers can add to our knowledge of the etiology of this disease. It is perhaps acknowledged to be an infection. I am very much interested in the bacteriology of this disease, in its immunology. Very little has been written, but some things have definitely been written in the last fifteen years on that subject. I should like to know if there is any evaluation of these points.

I should like very much to know, for I am one of the least of those who is sometimes called on in preventive medicine to give advice, how to avoid disease, how the public may be instructed to avoid such things as appendicitis. I should like very much to know more of the preventive side of this whole matter and if there is not time tonight if this is to be referred by the Academy to its appropriate committee for energetic and vigorous pursuit, I suggest a very strong effort be made to develop a preventive side of this subject, its bacteriology, its immu-

nology, as a very positive element in the handling of the whole thing from the standpoint of organized medicine.

DR. G. W. KOSMAK (New York City): Well, Mr. President and Members, I have been very much interested in what Dr. Krech has said and also in the general tenor of his paper, because he has taken a precaution to avoid some of the pitfalls of the other committee.

I noticed that he was very careful not to stress one factor in his investigation which gave the other committee a great deal of trouble and which created a good deal of disturbance, namely, that of preventability. I trust that when a new committee takes up its study, they will have the courage to investigate this particular phase of the situation. Although that feature created more or less dissension on the part of doctors in our maternal mortality study, I think it was the one thing which has directed as much attention to the need for reform as anything else.

I do not know whether I would have the courage to assert here what Dr. Krech failed to assert, or at least I didn't get it, that in these deaths there must have been a certain number that could have been prevented not by earlier attention, perhaps, but what might be called proper attention. These, I know, are debatable points, but unless we have the courage to attack them and to bring them to the front, we will not get far with our remedies.

That is a thought which I had in mind as Dr. Krech spoke, and I trust that it will not be forgotten by the new committee which is to investigate further this particular subject.

DR. EDWIN G. RAMSDELL (White Plains): Mr. Chairman, before referring to the analysis of my own series of cases of acute appendicitis, I cannot refrain from a word of

appreciation of the tremendous amount of work done by Dr. Krech in studying the enormous material from 14 different New York hospitals.

He has impartially, and with meticulous care, gone over the records of these cases in order to give us these interesting figures.

The object of my presentation is to contrast this study of Dr. Krech's with an analysis of 530 cases of acute appendicitis operated by one man, with a more or less uniform technic, in a community in which conditions can be more easily controlled than in New York City.

These cases were operated at the White Plains Hospital which serves a population group of 50,000 people and a group of doctors to whom the importance of early diagnosis and early operation has been repeatedly emphasized.

In conclusion I would like to refer to the total number of cases of acute appendicitis operated at the White Plains Hospital during the period covered by this study. There have been operated by other members of the Staff 775 cases with 28 deaths, or a mortality of 3.6 per cent. Including my own group of 530 cases the total number is 1305 cases, with 41 deaths, or a mortality of 3.1 per cent.

There are three distinct impressions which have been left with me as a result of this experience.

First, the findings at operation so often show a more extensive pathology than was indicated by the clinical symptoms.

Second, the outstanding factor in the appendicitis problem is early diagnosis and early operation.

Third, all credit should be given to the medical men of the community, the family doctors, who see these cases at the onset and get them to the hospital in time for early operation.

HEALTH NOT IMPROVED BY INSURANCE, NOR IS MORAL INTEGRITY

James M. Chalfont remarks that "cold statistics show that contrary to logical expectation, the health of the working classes, instead of becoming better, tends to grow worse under health insurance. And, as a corollary to that fact, the demand upon society for the care of the poor grows not lighter but heavier." By the way, whence comes the cry for all this improved medical care? Where are the newspaper reports of unattended sick, of sick who cannot get doctors' care because they are poor, of increase in morbidity and mortality rates? In America, days lost by sickness per year still average only 6.2, whereas in Germany in 1923 it was 9.2 and under insurance has risen to 16.5 days.

It has been reported in Germany, according to Chalfont, that Health Insurance has merely

added "parasitism to pamperism" and that social insurance is not only one of the major factors which has brought Germany to the verge of economic ruin, but it is undermining the fundamental honesty and moral integrity of the German people.

"Social insurance is today organized to fill the feed-trough of bureaucratic drones," says Dr. Ernst Liek of Danzig in *Medical Economics* for January, 1935.

Let us be gay! The era and the times change. Medicine will still be individualistic and an incentive when all the bothersome things of this transitional phase are over. In solitude and contemplation great thoughts take birth. Mass work, standardized thinking, and formularized therapy will never in the long run suit Americans.

THE DIAGNOSIS AND TREATMENT OF INTESTINAL AMEBIASIS

THOMAS T. MACKIE, M.D., F.A.C.P.

From the Department of Medicine, The Fifth Avenue Hospital

The importance of amebiasis is not generally appreciated. There are few diseases which are equally beclouded by misinformation and misapprehension. In the past it has generally been considered to be a tropical or subtropical infection rarely seen in the temperate zone. Surveys in different areas indicate that the climatic factor is relatively unimportant. The *Endamoeba histolytica* is widely distributed and its incidence in any district depends primarily upon the level of sanitation and upon the hygiene of its inhabitants. From 5 to 10 per cent of the population of the United States are infected, and amebiasis, therefore, constitutes a problem with which every practicing physician should be familiar. The major importance of the recent Chicago outbreak lies in the fact that many infected individuals have been scattered throughout the country and that they in turn may be responsible for the infection of others.

The *Endamoeba histolytica* is a parasite of the human colon. It multiplies within the intestinal tract and penetrates and destroys the tissues of the host. The motile forms or trophozoites are responsible for the pathologic changes in the body. Ultimately, certain of them become less active, develop an enclosing resistant membrane, and are passed in the feces as cysts. The cysts are the infective form of the parasite. They remain viable outside the body for considerable periods of time depending upon the conditions of environment. They withstand freezing, and even chlorine in the concentrations used for purification of water supply does not kill them. When these cysts are ingested by man, the contained amoebae are released within the small intestine and the cycle recommences. Active multiplication begins at once and the amoebae pass downward to take up their habitat in the cecum and colon. The trophozoites are very susceptible to lowered temperature and rapidly lose their motility and morphologic characteristics after evacuation from the body.

They are invariably inimical to the host. Their presence is always associated with tissue damage even though clinical evidence

is lacking.¹ Ulceration is the essential lesion. It is most extensive and most intense in the areas of relative stasis, particularly the cecum, the flexures of the colon, and less often the rectum. The cecum is always affected and with increasing severity the more distal areas are involved. The amoebae penetrate the depths of the intestinal glands to gain access to the submucosa. A small abscess results which ruptures into the lumen of the intestine. Peripheral extension occurs beneath the overlying intact mucosa causing secondary necrosis, sloughing, and ulcer formation. In severe cases this may penetrate the muscular coat and lead to perforation and peritonitis. In other areas the lesions are superficial and barely evident on gross examination. There is lysis and destruction of the superficial layers of the mucosa without typical ulcer formation and without much invasion or destruction of the submucosa.² At times the amoebae gain access to the radicles of the portal system and are carried to the liver where they give rise to the serious complications, amebic hepatitis and amebic abscess.

Conventional terminology has assigned to the infection the name of one of its less common clinical manifestations. This has created the erroneous impression that acute dysentery is the characteristic reaction of the host to the parasite. And it is to a very large extent responsible for the failure of the medical profession to appreciate the importance of the infection.

Apart from the less common phenomena, acute dysentery and amebic diarrhea, intestinal amebiasis does not produce a characteristic clinical picture. It may simulate by direct or by reflex action a great variety of gastro-intestinal conditions, and at times gastro-intestinal symptoms are lacking. In many instances the true diagnosis may not even be suspected until careful stool examination reveals the nature of the infection. Amebic infiltration of the cecum or colon may be mistaken for malignant disease. Amebic typhlitis frequently has led to operation for subacute or chronic appendicitis, a procedure which may be followed

by disastrous results, and reflex pylorospasm may lead to suspicion of gastric or duodenal ulcer.

Table I which Reed³ has prepared illustrates the great variety of presenting symptoms which are encountered. The patient may complain that his stools are constantly soft and unformed and perhaps slightly increased in number, or there may be periods of watery diarrhea without gross blood or mucus. Not infrequently there is constipation alone or alternating with looseness. Abdominal pain is very variable in incidence, in location, and in character. It is frequently referred to the region of the appendix, the cecum, and the ascending colon. It may be severe. During periods of loose stools or active diarrhea the pain may be colicky and midabdominal. Tenderness on palpation in the right lower quadrant is not uncommon. Tenesmus occurs only with involvement of the distal colon.

Even though the lesions are not sufficiently severe and extensive to produce these more characteristic symptoms, they may cause indirect effects which lead the patient to seek medical advice. Flatulence and abdominal distention occur frequently. Unexplained nausea and vomiting, neuroses, and asthenic states often accompany a chronic and unsuspected amebic infection.

DIAGNOSIS.—The diagnosis of intestinal amebiasis depends upon the demonstration of the organisms. In the presence of a classical acute dysentery it should not long be in doubt. There are frequent evacuations of fecal matter which is intimately mixed with small flecks of blood-stained mucus, the so-called "sago-grain stools." When there is involvement of the sigmoid and rectum with severe tenesmus, there may be additional passages of bloody mucus. Less commonly there is watery diarrhea with very little blood and mucus on gross inspection. Proctoscopic examination reveals characteristic changes in the rectal and sigmoid mucous membrane. It is studded with small ulcerations with normal mucosa intervening. Microscopic examination of curettings from these ulcerated areas, and of the flecks of blood-stained mucus in the stools reveals large numbers of the motile trophozoites.

Recognition of cases without acute symptoms is a more difficult procedure. It requires considerable training in protozoology and practical experience to differentiate accurately the pathogenic *Enda-*

TABLE 1.—MAJOR SYMPTOMS IN A GROUP OF FIFTY PATIENTS (Reed)

moeba histolytica from the nonpathogenic species frequently encountered in the stools of normal persons. James² has said: "Nearly twenty years of work on this subject has convinced me, and, I may add, others better qualified than myself, that the correct diagnosis in fresh material of intestinal amebiasis not associated with dysentery, and the proper identification of the four species of amoebae commonly found in the stools, is a task requiring long and special training, and is not to be entrusted, as it so often is, to the ordinary worker in the laboratory or the inexperienced technician."

It should be possible, however, for the physician to suspect the infection if sufficient stools are examined and certain rules are observed. The character of the stools is important. As a rule, encysted forms are found only in formed feces and the motile amoebae only when the stools are soft or liquid.

In the presence of diarrhea or dysentery the freshly passed and warm stool must be carefully examined for small particles of blood-stained mucus. One of these should be fished at once to a slide and examined before cooling occurs and the amoebae become inactive. The amoebae are not found in the fecal material.

A diagnosis of amebiasis must not be made unless the active forms show a sharp distinction between the food containing endoplasm and the clear glass-like ectoplasm of the pseudopodia; the amoeba must contain definite red blood corpuscles; and it must exhibit progressive motion across the microscopic field.

Demonstration of encysted forms frequently requires the examination of a series of stools passed on successive days. The cysts are not excreted constantly and from three to six specimens must be found negative before it is safe to assume that infection is absent. Since this phase of the life cycle is resistant, precautions against chilling are unnecessary. A thin suspension of the fecal matter in saline should be

TABLE II.—DIAGNOSTIC CHARACTERISTICS OF *ENDAMOEBIA HISTOLYTICA*

	Form	Where found	Morphology
Liquid stools	Trophozoites	Blood-stained mucus	Progressive motion; glass-like pseudopodia; contained red blood cells
Formed stools	Cysts	In the fecal mass	Saline Preparation: Blunt-end chromatoid visible; nuclei not visible Iodine Preparation: 4 nuclei paired at different levels with centrally placed karyosome, chromatoid not visible

made on a slide and covered with a cover glass. A similar preparation should be made using Donaldson's iodine. The cysts of *Endamoeba histolytica* are spherical bodies 7 to 12 μ in diameter. Nuclei are not visible in the saline preparation, but, if the specimen is fresh, a block of less refractile material with blunt, rounded ends may be seen within the cyst. This blunt-ended chromatoid body is characteristic of this species of amoebae. In the iodine preparation the chromatoid body is not seen, but the nuclei are stained and clearly visible. These are usually paired at different optical depths and each contains a centrally placed karyosome. The diagnosis of encysted *Endamoeba histolytica* should not be made unless all of these features are demonstrable.

TREATMENT.—Infected individuals must be treated irrespective of the presence or absence of symptoms. There may be gross ulceration of the intestine without significant clinical phenomena. The equilibrium existing between the parasites and the apparently healthy host is easily disturbed. Acute dysentery may occur with little or no warning and amebic hepatitis and abscess of the liver are seen without antecedent intestinal symptoms. Treatment, therefore, is essential for the protection of the infected individual. It is equally essential to prevent spread of the infection. However, it must have as its objective not only symptomatic cure but the complete eradication of the parasites. The latter is often difficult to accomplish. It requires knowledge of the pathology, familiarity with the mode and site of action of the various amebicidal drugs, and careful evaluation of the problem presented by the individual patient.

Many drugs have been used for the

treatment of amebiasis. No single one is adequate for every case and certain ones are associated with real dangers which are not generally appreciated. Emetine is excreted slowly and may cause serious poisoning when given in too large dosage or over too long a period. It produces myocardial damage which not infrequently has resulted in death from cardiac failure. Occasionally it is the cause of a serious peripheral neuritis. Consequently it must be used with strict adherence to the rules for dosage. The presence of organic heart disease demands even greater caution. Rising pulse rate, falling blood pressure, and widening of the cardiac diameters must be recognized as danger signals.

Emetine appears to act principally upon the amoebae in the tissues and although it will check an acute dysentery promptly, it does not eliminate the infection.⁴ The hydrochloride should be administered intramuscularly rather than intravenously or subcutaneously. The individual dose should never exceed 1 mg. per kilo of body weight per day, and the total dosage should not exceed 10 mg. per kilo of body weight. When given in this dosage the drug cannot be used again within six to eight weeks if the danger of cumulative poisoning is to be avoided.

Stovarsol and treparsol have been much used. Frequently, they have been the cause of serious arsenic poisoning. They are not efficient amebicides when given in amounts that are safe. Recently Reed⁵ and his associates have developed a relatively nontoxic arsenical, carbarsone, which is more efficient. It should not be used, however, when there is associated hepatic or renal disease.

The oxyquinoline derivatives are another group of drugs which have been widely used in the treatment of amebiasis. They include yatren, anayodin, quinoxyl, cliniofon N.N.R., and vioform N.N.R. They contain from 20 to 40 per cent of iodine which is partially absorbed and excreted in the urine. These drugs appear to act primarily upon the amoebae in the lumen of the intestine and are relatively ineffective against those in the tissues. They are efficient amebicides,^{6,7,8} nontoxic in therapeutic amounts, and, with the exception of vioform which is irritating to the rectal mucosa, may be given both by mouth and by rectum.

It should be apparent that therapy can be effective only when the amoebae within

the lumen of the intestine and those within the tissues are simultaneously exposed to lethal concentrations of actively amebicidal drugs. This frequently requires the use of two or more of these drugs in combination, and by different routes. The case with acute dysentery and extensive ulceration, should receive emetine. At the same time one of the other drugs should be given by mouth and by rectum. The average adult dosages of these preparations are: Carbarsone, 0.25 gm., orally twice daily for ten days, and retention enemata of a 2 per cent solution; anayodin, quinoxyl, and chiniofon, 1.0 gm., orally three times daily for eight to ten days and retention enemata of a 2 per cent solution. Vioform can be given only by mouth. The dosage is 0.25 gm., three times daily over a similar period. The patient should be confined to bed until there is clinical and proctoscopic evidence of healing. During the period of ulceration the diet should be soft and free from irritating residue. Bismuth subcarbonate is of value in lessening the diarrhea, and opium may be required to control pain and severe tenesmus.

The asymptomatic cyst passer may be

treated as an ambulatory patient using one of the drugs for oral administration. If this proves ineffective it is the writer's practice to institute the rigorous treatment outlined for the acute case. Emetine should not be used unless the patient is confined to bed and under careful supervision, and he should not indulge in strenuous exertion for a period of three or four weeks after its use.

Summary

1. Repeated negative stool examinations over a period of one to two years after clinically successful treatment are required before one is justified in assuming protozoologic cure.

2. Various modifications of therapy may be necessary to achieve this goal with the individual patient.

3. It is highly important for the physician to realize the wide distribution of amebic disease, its protean clinical phenomena, its hazard to the infected individual and to the community, and the difficulties and dangers of therapy.

Discussion

COL. ROBERT H. PIERSON, M.C., U.S.A. (Retired), Fayetteville: The subject of amebiasis has forced itself upon the attention of all physicians who have practiced in tropical or semitropical countries. Surgeons of the United States Army and Navy have been brought in contact with this disease since the time of the Civil War.

Records of the Civil War are of little value as diagnoses were uncertain. All enteric diseases were grouped together. There was no clear differentiation between the dysenteries and typhoid fever. The differentiation between amebic and bacillary dysentery was unknown.

During the early occupation of the Philippines amebic dysentery was known as such and was a dreaded scourge. Troops were stationed throughout the provinces in small towns where sanitary conditions were of the worst. Amebic dysentery was common. The cases were severe. About 5 per cent developed liver abscess.

At that time Colonel Thomas Rhodes, Medical Corps, U. S. Army, perfected the operative technique for liver abscess. His monograph on that subject was a classic. Medical treatment was ineffective. Many medicines were used. None of them was of much use. The most effective measures were those for prevention of the disease. When a patient had once become infected he was simply unfortunate. The outcome of his disease was not greatly determined by any treatment then available.

In the Philippine Islands today our troops do not suffer greatly from amebic dysentery. During a tour of two and a half years during which I was in command of a hospital of one hundred and fifty beds on the Island of Corregidor, at the mouth of Manila Bay, there were only two or three admissions for amebic dysentery. The cases were mild and quickly responded to treatment. During the same period there were but few admissions for this cause at the Sternberg

Hospital at Manila. There was but one case of amebic liver abscess.

The change has come about through the use of pure water supplies, chlorination of water, discontinuance of the use of uncooked foods, and effective medicinal treatment of early cases.

Natives of the tropics have considerable racial, natural, or acquired immunity to amebiasis. In the Philippine Islands it was difficult to impress the natives with the necessity for boiling drinking water. They drank unsterilized water and had no ill effects. They could not understand why the white man must drink boiled water. Sir Patrick Manson remarked that on a European coming to the tropics the grossly unsanitary conditions under which the natives lived made an immediate and profound impression. Such conditions would bring death to the foreigner but under them the natives not only lived but thrived. They have a high degree of immunity.

There are many kinds of amebae. They are common enough in stagnant water in both tropical and temperate climates. There are only a few kinds which are harmful to men. In the intestinal tract three or four kinds may be found which are simple saprophytes. The mere fact that amebae of some kinds are present in the stools means little.

Amebae attain luxuriant growth in tropical countries. In temperate climates they are less numerous and less vigorous. While some surveys have brought out the fact that from 5 to 10 per cent of the population in temperate climates have amebae in the intestinal tract, the incidence of amebic dysentery is very low.

The United States Army has troops scattered in the Second Corps Area, throughout New York, New Jersey, and Pennsylvania. They go to the various training camps and are scattered throughout the various Conservation Camps. The report on amebic dysentery is negative.

The Attending Surgeon, New York City, treated but two cases last year. Neither of them was a soldier. One was the daughter of an army officer who had visited Chicago. Her father, who has served in the tropics, knew the disease. He brought her at once to the Attending Surgeon. Her cure was prompt.

The other case was that of a man who had contracted the disease in Chicago in June, 1933. He had been to several physicians without diagnosis of amebiasis being made, though several samples of stools had been sent to laboratories. The reports were negative. At the attending surgeon's office the stools were found to be heavily infected. There were four amebae in the first specimen examined, in the first field seen under the microscope. Cure was uneventful.

Examination of the stools, if the diagnosis of amebiasis is to be determined, must be made of specimens which are not only fresh but warm. It is easiest to have them made when patients are in hospital. At the Attending Surgeon's office in New York examinations are made of fresh stools which are passed at the dispensary.

The Regional Director of the State Board of Health of New York has issued instructions for physicians who submit stools for examination to have the specimens put in thermos bottles and carried immediately to laboratories.

Records of the New York City Board of Health for a period from January 1, 1934, to September

1, 1934, show reported cases of dysentery as follows:

Bacillic dysentery—Cases 155; Deaths 8.

Amebic dysentery—Cases 55; Deaths 5.

Of the amebic dysentery cases:

6 originated in N. Y. City or from sources undetermined.

29 originated in Chicago.

20 originated in other states or countries.

Several were from New Jersey; 4 from Florida, others scattered—Texas, Louisiana, Italy, Germany and China.

New York City has a water supply from excellent sources. The water system is good. Incidence of amebic dysentery is correspondingly low.

It would appear that where the sources of water supply are questionable and where systems of purification are imperfect there is a correspondingly higher rate.

The incidence of a high rate of infection among visitors to localities where they have contracted amebic infection brings up an interesting question of local immunity. It is quite possible that in places where the ameba histolytica is present the local inhabitants have acquired a relative immunity. This would be similar to the immunity enjoyed by natives of the Philippine Islands and China, where natives are relatively immune but visitors are susceptible.

TREATMENT

Amebic ulcers tend to burrow beneath the surface. Treatments by medicines either given by mouth or by enemas touched only the surface. Old treatments with morphine and bismuth only relieved immediate symptoms. The ameba histolytica remained undisturbed.

The first advance in treatment came when ipecac in massive doses was used. This treatment was so severe that it was almost worse than death. The next great advance in medicinal treatment came with the use of emetin. It was possible to use a drug which was a specific against the ameba histolytica. There was something which would kill the parasite without killing the patient. It is as much a specific for amebiasis as quinine is a specific for malaria. With the use of emetin cases were treated earlier and were cured. Amebic dysentery could be controlled.

Objections to emetin are that it has to be given by hypodermic. The injections are rather painful. The drug has some harmful effect upon the heart muscle but most patients suffered no ill effect. The cure was far less dangerous than the disease.

Ten years ago emetin was the main reliance of the physician who treated cases of amebic dysentery. It is still one of the therapeutic mainstays. It is indicated in cases where there is any kidney involvement or where there is suspicion of liver abscess. It may also be required in some cases of long standing which do not respond to arsenicals.

The arsenical most favored by physicians with whom I have been brought in contact is Carbarsone. It was first prepared by Ehrlich. This drug is given by mouth. Two two-and-one-half grain tablets four times daily, for an adult, for ten days. To be effective it is given in nearly twice the recommended dose of one tablet four times daily.

Before treatment the patient should have the urine examined. Some physicians also have the eyes examined. Palpation and percussion will give the liver outlines. If there is suspicion of liver abscess or evidence of nephritis it is contraindicated. In such cases use emetin.

Reports from several physicians practicing in the Philippine Islands and China are to the effect that Carbarsone has almost completely replaced the use of emetin.

Stovarsol was one of the first arsenicals used. It has been discarded because it is too toxic.

There are a number of other arsenicals prepared by various manufacturing druggists. Among them are:

Chiniofon (Sodium iodox quinolin sulphate).
Anayodin, and others.

While amebic dysentery is not now the menace to white residents of the tropics that it was a few years ago it is still a disease to be carefully avoided. It is less prevalent in temperate climates than in tropical or subtropical climates but it is still enough of a menace to make precautions very advisable for persons who are traveling.

The old English custom of drinking nothing which has not been boiled or does not come

in a bottle is worthy of merit. In addition it is well to avoid lettuce and other uncooked vegetables.

Infections with amebae are not the only ones which endanger. In this part of the country bacillary dysentery is three times as common as the amebic variety. There are also dangers from other enteric infections to be considered. Here infection with typhoid and paratyphoid are not uncommon. In the Far East the danger of infection with cholera is the greatest danger of all.

While the incidence of amebic dysentery in New York City is not high (only 55 cases in 8 months in a population of over 7,000,000), the death rate of 5 out of the 55 cases was too high. It may be attributed to delayed diagnosis and ineffective treatment. There was but one case of liver abscess.

We now know that infection of the intestinal tract with ameba is not uncommon. We know that in temperate climates amebic dysentery is not yet a therapeutic menace. We should, however, be on the alert to detect these infections. If they escape detection and do not receive specific medication the prognosis for the patient is none too good.

OHIO-MICHIGAN-INDIANA-ONTARIO-NEW YORK-PENNSYLVANIA SECTIONAL MEETING, AMERICAN COLLEGE OF SURGEONS

The Ohio-Michigan-Indiana-Ontario-New York-Pennsylvania sectional meeting of the American College of Surgeons will be held in Cleveland, Ohio, on Thursday and Friday, April 4 and 5 next. Headquarters will be at the Hotel Statler. An active Committee on Local Arrangements, with Dr. William E. Lower as chairman, and Dr. John Dickenson as secretary, have plans well in hand for an excellent meeting.

Following is a preliminary outline of the entire program:

THURSDAY, APRIL 4, 1935

- 8:00- 9:00 Registration.
- 9:00-12:00 Operative Clinics.
- 9:30-12:00 Hospital Conference.
- 12:30- 2:00 Medical Motion Pictures.
- 2:30- 5:00 Hospital Conference.
- 5:00- 5:30 Annual Meeting, Fellows of the College.
- 7:00- 8:00 Medical Motion Pictures.
- 8:00-10:30 Scientific Session, General Surgery.
- 8:00-10:30 Scientific Session, Eye, Ear, Nose and Throat Surgery.
- 8:00-10:30 Hospital Round Table Conference.

FRIDAY, APRIL 5, 1935

- 9:00-12:00 Operative Clinics.
- 9:00-11:00 Cancer Clinic.
- 9:30-12:00 Hospital Conference.
- 12:30- 2:00 Medical Motion Pictures.
- 2:30- 5:30 Scientific Session, General Surgery.
- 2:30- 5:30 Scientific Session, Eye, Ear, Nose and Throat Surgery.
- 2:30- 5:00 Hospital Conference.
- 8:00-10:00 Community Health Meeting.

Some of the distinguished visitors who will

be present on this occasion are: Dr. Franklin H. Martin, Chicago, Director General, American College of Surgeons; Dr. Frederic W. Bancroft, New York City, Associate Professor of Clinical Surgery, Columbia University College of Physicians and Surgeons; Dr. George Crile, Cleveland, Director, Cleveland Clinic Foundation, and Chairman, Board of Regents, American College of Surgeons; Dr. Winchell M. Craig, Rochester, Neurosurgeon at Mayo Clinic; Dr. Robert B. Greenough, Boston, President, American College of Surgeons; Dr. LeRoy Long, Oklahoma City, Director, LeRoy Long Clinic; Dr. John O. McReynolds, Dallas, Ophthalmic and Aural Surgeon, St. Paul's, Parkland, and Methodist Hospitals, Scottish Rite Hospital for Crippled Children; Dr. Charles L. Scudder, Boston, Consulting Surgeon, Massachusetts General Hospital; Dr. Frederic A. Besley, Waukegan, Professor of Surgery, Northwestern University Medical School; Dr. Malcolm T. MacEachern, Chicago, Associate Director, American College of Surgeons, and Director of Hospital Activities; Robert Jolly, Houston, Superintendent, Memorial Hospital, and President, American Hospital Association; and Dr. M. N. Newquist, Chicago, Department of Industrial Medicine and Traumatic Surgery, American College of Surgeons.

A cordial invitation to attend this most interesting meeting is extended not only to the Fellows and hospitals of the various states and province included, but to the entire medical profession at large.

TUBERCULOSIS HOSPITAL AND FAMILY PHYSICIAN

GEORGE W. WEBER, M.D.

From the Ulster County Tuberculosis Hospital, Kingston

The problem of intelligent co-operation and the maintenance of friendly relations between members of the medical profession and field workers engaged in the fight against tuberculosis has always been a serious one, and it is evident that a satisfactory solution of this problem would not only undoubtedly benefit both these groups, but also the public at large.

The physician of today justly views with some alarm the perceptible leaning toward state medicine and the ever increasing number of free clinics which inevitably threaten encroachment upon his private grounds. The field worker, on the other hand, feels that he is successfully fulfilling his mission only when he expands his sphere of activity as widely as possible. Occasionally he will overstep into the physician's domain, and even if this is not always deliberate, sooner or later consequently he will encounter indifference, and perhaps antagonism. The results of the mutual distrust thus engendered have been unfortunate. In many instances the clinic staff, perhaps considering themselves the sole possessors of wisdom on tuberculosis, and always eager for impressive statistics, examine, with or without the physician's permission, anyone who walks into the clinic.

In retaliation a physician who suspects tuberculosis will send his patient not to the clinic, but to the general hospital for an x-ray; or, this proving beyond the patient's means, he contents himself with sending a specimen of the sputum to the State Laboratory. Too great dependence upon this method of diagnosis may be one of the reasons why a majority of cases admitted to the hospitals are in a far advanced stage, as it is a well known fact that in many incipient lesions the sputum may be repeatedly negative. However, there is no doubt that the medical profession as a whole does realize the importance of field work, the necessity of extensive x-rays, and the help which the facilities of a well conducted tuberculosis clinic can supply. In the case of the clinics conducted periodically by the Division of Tuberculosis of the State Department of Health throughout New York State, the number of patients sent each time by private physi-

cians gives conclusive proof of how much such service is appreciated. At these clinics the patient is examined and x-rayed, but no information is given to him. Within a few days the report, with the diagnosis and eventual recommendations, is sent to the physician, and the final decision left to him, even if admission to the hospital has been advised.

But now what usually happens when a physician sends his patient to the local hospital clinic? He will receive a report of the examination, it is true, but, if the diagnosis happens to be positive, the patient is urged by the staff to enter the hospital for protracted treatment, and the physician will probably lose all track of him from that moment. The hospital staff proceeds to examine all the contacts, requesting the members of the patient's family to come to the clinic, not only for a first examination but, after that, also for check-ups. Even if the patient recovers and leaves the institution, he and his family are still kept under its supervision. And through all this the physician, who was responsible for the original diagnosis, is left completely out of the picture. This does not seem ethical or even logical. After all, if a physician refers a surgical case to the surgeon for an operation, or any other case to the specialist, he does not lose his patient forever, even if prolonged treatment has been required. Reginald Fitz in an article, "Problems of Pulmonary Tuberculosis in General Practice,"¹ says: "The tuberculosis specialist takes care of the patient during an acute phase of a chronic disease, whereas the family physician should take care of the patient during his entire lifetime."

Tuberculosis should not be monopolized by either group. The issue is too important, and certainly the field is wide enough to engross the activities of both. Only it is necessary that the effects be properly co-ordinated and not wasted in petty controversies. This is obvious to anyone interested in the subject.

Naturally during two years of clinic work in our hospital, we have been faced with countless versions of the problem presented above, and in striving for the co-operation and good will of the general

Before treatment the patient should have the urine examined. Some physicians also have the eyes examined. Palpation and percussion will give the liver outlines. If there is suspicion of liver abscess or evidence of nephritis it is contraindicated. In such cases use emetin.

Reports from several physicians practicing in the Philippine Islands and China are to the effect that Carbarsone has almost completely replaced the use of emetin.

Stovarsol was one of the first arsenicals used. It has been discarded because it is too toxic.

There are a number of other arsenicals prepared by various manufacturing druggists. Among them are:

Chiniofon (Sodium iodox quinolin sulphate).
Anayodin, and others.

While amebic dysentery is not now the menace to white residents of the tropics that it was a few years ago it is still a disease to be carefully avoided. ULSTER COUNTY TUBERCULOSIS HOSPITAL

Kingston, N. Y.

January 30, 1935

My DEAR DOCTOR:

The following is the periodical report of the condition of your patient Patsy M., who is at present in our Hospital.

On Admission			
Temp.	Pulse	Weight	Sputum
99.8-100	92-100	122¾	Gaffky 6
At Present			
Temp.	Pulse	Weight	Sputum
98-98.6	80-90	131¾	Gaffky 5

Present General Condition and Physical Examination

The left lung appears to be clear. Right lung: Anteriorly, slight hyper-resonance over the supra and infraclavicular regions. Breath sounds slightly diminished in this area, and normal toward the base. Posteriorly, hyper-resonance in the upper third and at the periphery down to the base. The breath sounds are distant, almost absent. No adventitious sounds. No shifting level at the base and no succussion. Patient coughs and raises much less than on admission. Has had no more hemorrhages. General condition is much improved.

X-Ray Findings

There is a partial pneumothorax of the right side. The upper lobe is more collapsed and atelectatic, while the lower lobes are almost completely expanded. The upper lobe still shows the presence of a cavity which, however, is smaller than on previous examination. There are two adhesions at the level of the first and second ribs which seem to interfere with a complete and satisfactory collapse of the cavity. No fluid is present at the base. The left lung is clear. No deviation of the heart or mediastinum.

Treatment

Artificial pneumothorax and strict bed rest. If the adhesions should prevent further collapse and closure of the cavity, their resection through a closed pneumolysis should be considered in the near future.

Remarks and Recommendations

The patient's wife and children have been examined and found negative. It would be advisable to have his parents examined also in order to rule out the members of the family as the source of infection. The patient's family has been notified of this report and has been referred to you.

.....
Medical Superintendent.

practitioner, we have gradually evolved a simple system of routine which not only considers the physician *at every point, but enlists his valuable aid as well*. Although incomplete and lacking in many respects, the details of this system may possibly afford suggestions to other institutions.

(1) First of all, we never examine a patient without the knowledge and consent of his physician. Request cards for examination of the type used by the State Clinic are supplied to each physician, and every patient must present one. An occasional exception is made when a patient arrives at the hospital without one (the hospital is not easily accessible to persons without automobiles), and in this necessity we get the permission from his family physician by telephone. If the patient has no physician and cannot pay for one, we refer him to the Relief Office which will provide for him. To our knowledge, no patient has ever refused to follow this procedure.

(2) All information regarding his examination is withheld from the patient. He is again referred to his physician, who as a rule receives our report within 24 hours. In the case of a positive diagnosis with hospitalization indicated, we feel that the family physician has a better chance of convincing both patient and family of this necessity.

(3) The amount to be paid for the examination is left to the physician's discretion, as he is in a better position to know the financial status of his "families." Although it is most important in our work to avoid the imposition of fees, yet there are a few who could afford to pay a small sum. Therefore on one corner of the card are printed the figures 0-1-3-5-10, one of which is checked by the physician. It is true only a very small number pay three or five dollars, but at least with this system we prevent abuses on our services and, more important, we avoid displeasure on the part of the local hospitals and physicians who may have x-ray equipment.

(4) A small photograph of the x-ray is attached to the report. (See Chart 1.) The written report alone of an x-ray, no matter how detailed, is never wholly satisfactory to the practitioner, who, as a rule,

glances quickly to "diagnosis." Moreover we feel that if he could visualize the x-ray, his interest in the physical examination would be stimulated and he would derive greater satisfaction from a correct diagnosis. The ideal way would be for us to send him a full size copy of the x-ray, but since this is impractical because of the expense involved, we think that the small copy serves as a very good substitute. We use for the purpose a Kodak adapted for making lantern slides and from these, copies are printed on ordinary sansitized paper. The extra cost of a few cents, and the few minutes required for each copy are well spent, as this small photograph reproduces faithfully the same contrasts as the original x-ray and it is also clear enough to give, together with the written report, a detailed idea of the character and extent of the lesion. Naturally this is used only for cases showing any pathological condition of the chest, whether tuberculous or not.

(5) During hospitalization and also after discharge, the physician receives periodic reports with a copy of the latest x-ray, (Chart 2), giving details of his patient's condition, as well as information regarding the prognosis, the type of treatment advisable, and so on. In this way he keeps in touch with every phase of the disease and is able to confer competently with the relatives, who in the meantime have been notified by us of each report. While the clinic staff is not excluded entirely from direct interviews, still we have found from experience that the family physician, with full knowledge of the case, has often been more successful than we have in obtaining consents for pneumothorax, or other surgical intervention, or even for the examination of all the contacts in a family.

Thus, by demonstrating that our aim is service and not competition, we believe that a closer and more efficient relationship is being established between the medical profession and our hospital. All we ask in return is more interest in the serious problems of tuberculosis and support in the attempt to solve it.

The Medical Attitude Explained

The Report of the Reference Committee of the House of Delegates of the A.M.A. furnishes a concise and unequivocal explanation of the medical profession's opposition to compulsory health insurance. Regardless of economic factors, the primary concern of organized medicine must be betterment of the public health and the advancement of medical science. These aims are incompatible with a system that regiments physicians and sets up a lay bureaucracy in control of practice.

The element of compulsion is a vicious one in any program for budgeting the costs of medical care. It destroys the essential element of professional confidence, whether the plan is administered by Federal, State or local agencies. It induces malingering on the part of unwilling subscribers who insist on some return for their forced contributions.

Although the report of the President's Committee on Economic Security embodies some of the principles enunciated by the A.M.A., it is in many respects unacceptable. The Wagner bill is also guilty of grave departures from the ten points laid down by the profession as the basis of any satisfactory program for the distribution of medical care. Physicians recognize the need for Federal aid in supplying the indigent with basic necessities during an emergency; but they do not believe that adequate medical relief can be provided

except under medical direction. The Wagner bill gives the lay Department of Labor control over the care of crippled children and the advancement of child and maternal health. It fails to specify any medical personnel on the social insurance board, which will handle many essentially medical problems.

The Reference Committee reiterates what the profession has always held: there are no social cure-alls any more than there are panaceas for physical ills. A sound sociological program, no matter what its aim, must be based on local conditions—on the economic, mental, and moral character of a community rather than uniform national legislation.

There are over one hundred and fifty plans on trial in various sections of the country, some giving a record of successful operation unequalled by compulsory health insurance at its best. Surely it were wiser to extend the best of these experiments than to force the country to accept a system which organized medicine considers "fatal to medical progress" and destructive of quality in medical care.

Schools for Scandal

The roots of most quackery lie in the sectarian schools that make fortunes advertising a short cut to the practice of healing. In many cases the ignorant matriculants are honestly unaware of the limitations of

the methods taught them. The proffered degree convinces them of the authenticity of the curriculum and they embark upon what is in fact the illegitimate practice of medicine, sustained by the diploma of their spurious alma mater.

Although the Education Law is explicit in its ban on degrees unauthorized by the Legislature or the Regents, several schools of chiropractic and naturopathy have openly flaunted the statutes for many years. Within the past few months their immunity has been abruptly terminated. A concerted campaign by the State Department of Education, Deputy Attorney General Ullman and his staff and the District Attorneys of New York City has already resulted in the conviction of officials of the Eastern Chiropractic Institute; and the heads of two other institutions—the New York School of Chiropractic and the American School of Naturopathy—are on trial. The notorious Benedict Lust is one of the defendants in the latter action.

Alarmed by this turn of events, the friends of naturopathy are attempting to allay the threat of prosecution by amending the law. There is more than a touch of humor in the Howard-Kirnan bill, which authorizes the establishment of colleges of "natural therapy." The prescribed curriculum includes cibology, hirudology, dietology, clysmology, laxatology, potiology, rotology, and electrolysis, among other subjects. Do we hear envious sighs from the melancholy Mock Turtle, who only had the advantages of Ambition, Distraction, Uglifications, and Derision?

There is little likelihood that the Legislature will add a monstrosity like the Howard-Kirnan Act to the statute books. The current campaign against unauthorized schools indicates that the state has had enough of these incubators of quackery.

Early Detection of Poliomyelitis

It appears as if the dread sequelae of poliomyelitis may soon become the exceptional rather than the usual hazards in the treatment of this malady. Considered primarily as a disease of infancy, it has taxed the resources of our health authorities who have been confronted, in the past decade, with its spread among older chil-

dren as well as among adults. The uncertain manner in which the disease is transmitted from person to person has considerably handicapped preventive medicine. Whether the portal of entrance is through the upper air passages solely or whether the virus gains entrance via the intestinal tract, is still matter for further investigation; both views have supporters capable of furnishing convincing proof.¹

With the advent of serotherapy for poliomyelitis and the excellent results reported from its use, the family physician once more assumes an important place in medicine's attempt to obviate the frightful paralyses which too often ensue following an attack of this affliction. It is conceded that at present, serotherapy affords the greatest promise of success when employed very early in the course of the disease. Consequently the establishment of an accurate diagnosis at the soonest possible moment adds immeasurably to the possibility of securing a complete cure by this method of medical care.

Wieland² stresses the importance of the preparalytic symptomatology of poliomyelitis. He described two forms which the prodromal symptoms may assume. One type is characterized by the appearance of muscular weakness which may either be generalized or confined to certain muscle groups. There may be merely an unsteady gait or twitchings of the muscles in the arms and legs; on the other hand, the weakness may be so pronounced as to cause a temporary collapse. In this type, the patient may also present indefinite rheumatic pains.

The other variety of the prodromal stage in poliomyelitis is more definitely diagnostic since the symptoms point to a neurological involvement. The disease should be suspected when pain is present upon pressure over the great sacrosclatic foramen, the site of emergence for the sciatic nerve, (the sign of Lasègue); when there is pain in the back and along the spinal column, and when nuchal rigidity is evident upon examination.

In the abortive cases of poliomyelitis,

¹ Toomey, J. A.: Poliomyelitis, *Jahrbuch f. Kniderheilk.* 143: 353, 1934.

² Wieland, E.: Prodromal Stage of Poliomyelitis and Its Significance for Early Diagnosis and Therapy, *Jahrbuch f. Kniderheilk.* 143: 321, 1934.

the prodromal stage may be entirely absent and recourse must then be had to the characteristic findings in the cerebrospinal fluid. In any event, the early detection of this lesion depends largely upon the clinical acumen of the physician, and, since serotherapy must be started as soon as possible, the knowledge of the earliest symptoms of poliomyelitis is of the utmost importance.

Xylose

The sugars available for use as fuel for the body are characterized by a special chemical constitution of which the essential factor is a skeleton consisting of six carbon atoms. Similar compounds, but possessing more or less carbon atoms, can be synthesized in the chemical laboratory, or they are found to exist in nature. Artificial production can be carried out only at very great expense, and up to very recently even those already existing in natural combination were available only after tedious and costly extraction processes. Newer developments in sugar chemistry have resulted recently in the separation of a 5 carbon sugar (xylose), which is obtained from wood pulp. This product possesses practically all the characteristics of ordinary sugar, being sweet, readily soluble, and harmless, but the selective action of the body is such that it passes through the liver without the slightest absorption and is excreted quickly through the kidney.

Hence it forms an ideal substance for testing renal function. Fishberg and Friedfeld¹ in a recent article show that if a fixed amount fifty grams in an adult, is given as a lemonade in the presence of normal kidney function, it will appear within three hours in the urine at a concentration of at least two per cent, and may be detected by a simple quantitative Benedict reaction.

Slight alterations of kidney function result in modification of this figure. Since the body cannot use this substance in any way whatsoever, it is an excellent method of determining blood volume, since the original concentration injected intravenously is known, and its concentration in the blood can be determined. Due to its sweet taste and non-participation in assimilatory processes, it would seem as if it would furnish an excellent non-fattening sugar and be harmless to diabetics. The future applications of this compound would seem to be almost limitless.

A Good Example to Follow

Elsewhere in this issue appears a short original article by Dr. George W. Weber, "Tuberculosis Hospital and Family Physician," from the Ulster County Hospital at Kingston. The report merits serious consideration because it exemplifies how public health work in relation to tuberculosis may be carried on with the full integration of the family physician in the procedure.

The hospital utilizes the family physician to the fullest extent. No information is given either to the patient or any lay friend by the hospital. If the patient comes to the hospital of his own accord, the hospital contacts the family physician, or if there is no family doctor in attendance, then the hospital sees to it that the Relief Office provides one. The charges that are made are arranged through the family doctor, and during the patient's stay in the institution progress reports are sent to the family doctor.

Here there is a developed plan which should be reduplicated in every other part of the State. Were it more prevalent the mutual distrust between practicing physicians and hospital authorities would be lessened and eventually would disappear.

MEDICAL BROADCASTS

The following talks will be broadcast over WABC under the auspices of the New York Academy of Medicine and the Medical Society of the County of N. Y.

Thursday, March 21 at 11 15 A. M., 15 minutes
Subject: Preventing Communicable Diseases in Children

Speaker: Dr. Murray H. Bass, Associate
Pediatrian, Mt. Sinai Hospital, New York

Thursday, March 28 at 11 15 A. M., 15 minutes

Subject: If You Had An Accident

Speaker: Dr. Robt. H. Kennedy, Surgical
Director, Beekman Street Hospital, New York

Society Activities

Insurance Information Assured

"Over half the misery of this world is caused by the drawing of wrong inferences." The Council and its Executive Committee are ever conscious of the constant rumbling of interrogatory criticism by members concerning the Group Plan of Insurance against alleged malpractice. Occasionally this rumbling becomes articulate in the form of direct questions from members or from County Societies. Judged by the strange and unexpected qualities of most of these questions, they have been framed by those who misunderstand the Group Insurance Plan or who

have been misinformed concerning its operations. Misinformation and misunderstanding can be avoided or corrected by complete demonstration of the plan and full understanding. Well arranged addresses and a quantity of lantern slides are available to any component County society in the State, for any meeting, without cost to that society. If the secretary is addressed a few weeks in advance our insurance representative or some well informed member of the Council will be happy to present the subject and answer all queries. D. S. DOUGHERTY, M.D., *Secretary*

Committee on Legislation

BULLETIN NO. 7, FEBRUARY 22, 1935

The following bills have been introduced since the issuance of our last bulletin:

Senate Int. 957, Howard; Assembly Int. 1339, Kirnan, adds new article to the Education Law, authorizing establishment of colleges of natural therapy. Referred to the Education Committee.

This is not a chiropractic bill; it originated with some physician of the old school residing in Brooklyn. An excellent description of the bill lies in its definition of a "doctor of natural therapy": "A doctor of natural therapy shall be deemed to be a person who has successfully taken a course of study prescribed by the Regents of the University of the State of New York in a college recognized by it in 1. Hydrotherapy (mineral waters); 2. Balneology (mineral bathing); 3. Cibology (preparation of foods for the sick); 4. Dietology (dietetics and metabolism); 5. Hirudology (application of leeches); 6. Hygiene (sanitation, sterilization, antiseptic and aseptic work); 7. Clysmology (lavage of stomach, bladder and colonic irrigation); 8. Laxatology (the relaxation of muscles, tendons, joints); 9. Massage (kneading, exercise, under water exercise); 10. Phlebotomy (application of cupping, plasters, salves); 11. Potiology (drinks, teas in sickness); 12. Rotology (rotation of various parts of the body to relax and release); 13. Electrolysis (removal of hair by electricity); 14. Scalp treatment (to prevent hair falling and baldness); 15. Physiotherapy (the application of diathermy, ultra violet and other radiations under physicians orders)." The Legislative Committee has filed its disapproval of the bill.

Senate Int. 961, Buckley, amends the Judiciary Law by providing jury duty exemption only for lawyers, doctors, clergymen, firemen, policemen, U. S. soldiers, and sailors and ships' officers. Referred to the Judiciary Committee.

Physicians and surgeons having patients requiring daily professional attention are exempted in this bill. The Legislative Committee approves the bill with the recommendation, however, that the limiting phrase be deleted and that all physicians be exempted.

Senate Int. 973, Feld; Assembly Int. 1214, McGrath, amends the Education Law by providing after June 1, 1941, four-year course of study only shall be acceptable for admission to examination as a pharmacist. Referred to the Education Committee.

Senate Int. 1058, Byrne, amends the Civil Practice Act by providing in personal injury actions where court orders a physical examination, party, if a female, may have right to be examined in presence of her own personal physician and such relative or other person as court directs. Referred to the Codes Committee.

Senator Fearon had a similar bill last year. Approved.

Senate Int. 1077, Twomey; Assembly Int. 1473, Alterman, amends the Mental Hygiene law by providing no officer, employee or visitor of state institutions or the Mental Hygiene Commissioner shall be liable for damages in a civil action if he shall have acted in good faith with reasonable care and upon probable cause. Referred to the Health Committee.

Senate Int. 1149, Esquirol; Senate Int. 1179, Esquirol; Assembly Int. 1321—Breitbart, Domestic Relations Law, empowering court to order the making of one or more blood-grouping tests by a physician and permitting result to be received in evidence. Referred to the Judiciary Committee.

Approved. The Assembly bill has been reported out of committee.

Senate Int. 1167, Deyo; Assembly Int. 1486, Bush, adds new article to the Mental Hygiene Law for sterilization of mentally deficient or diseased persons when in opinion of superintendent or director of any state hos-

pital or institution it will be for best interest of innuante and society so to do. Referred to the Health Committee.

Senate Int. 1221, Nunan, Public Health Law, prohibiting the bringing into state or sale of flour to which oxides of nitrogen or nitrus acid or nitrates or chlorine or any other chemical bleaching agent has been added, unless package or container bears label "bleached." Referred to the Health Committee.

Senate Int. 1226, Wojtkowiak, adds new section to the Penal Law making it a misdemeanor to apply any coloring substance to raw meat offered for sale or to sell such meat chemically or otherwise colored. Referred to the Codes Committee.

Assembly Int. 1295, Doyle, creates temporary state of increasing use in childbirth and referred to the "e."

Disapproved on the ground that the Department of Health and the State Society have been collecting data on this subject for two years or more and we believe that a commission of this kind could add nothing to what they have done.

Assembly Int. 1306, Ehrlich, amends the Public Welfare Law by providing person in need of medical care other than hospital treatment shall be attended by his family physician or one of his own choice practicing in vicinity, who shall be employed by public welfare official; otherwise such official shall select the physician, charge to be \$1.00 for each office call and \$2.00 for each house call, and for each obstetrical case in the home, \$25.00. Referred to the Relief and Welfare Committee.

The Legislative Committee approves of the first part of this amendment which provides that every welfare patient shall have the privilege of selecting his family physician, but disapproves of the latter part in which is stated the amount to be paid for certain services.

Assembly Int. 1358, J. E. Stephens, adds new section to the Insurance Law providing no life insurance policy shall be issued unless it provides that after death of insured sum not exceeding 10% of face value and in no event more than \$500 shall be paid pro rata to any claimants for medical aid, nursing and attention and funeral expenses. Referred to the Insurance Committee. Approved.

The Legislative Committee has filed with the proper legislative bodies its approval or disapproval of the following bills in addition to those mentioned above:

APPROVED

Senate Int. 19, Print 774—Medical Abuses

Senate Int. 20, Print 943—Occupational Diseases

Senate Int. 545—Sale of poisonous drugs

Senate Int. 546—Misbranding certain poisons

Senate Int. 547—Manufacture and sale of proprietary medicines

Senate Int. 548—Manufacture and sale of drugs

Senate Int. 575—Relative to milk and milk products

Senate Int. 592—Public welfare districts, medical care

Senate Int. 693—Mental institutions, purchase of supplies

Senate Int. 754—Payment of medical expenses by executor

Senate Int. 869—Decedent Estate Law, medical expenses incident to injury causing death

Senate Int. 898—Medical treatment of pupils with defective sight or hearing

Assembly Int. 764—Labeling cosmetics

Assembly Int. 765—Broadcasting surgical or medical advice

Assembly Int. 1106—Misbranding drugs

OPPOSED

Senate Int. 571—Special nursing care for blind

Senate Int. 572—Amount to be spent on needy blind person

Senate Int. 577—"Home relief" to include eyeglasses, etc.

Senate Int. 589—Practice of electrolysis

Senate Int. 616—Relative to jury duty

Senate Int. 707—Hospitalization of members of city fire depts.

Senate Int. 794—Indigent children to be furnished with eyeglasses, etc.

Senate Int. 802—For licensing school psychiatrists, etc.

Assembly Int. 699—State Insurance Fund, payment of expenses

Assembly Int. 793—"Funeral expenses" to include cost of headstone

Assembly Int. 1061—State to be responsible for public care of person having no settlement in any public welfare district

Assembly Int. 1152—Pasteurization and bottling of milk

ACTION ON BILLS

Senate Int. 20, Print 943—Occupational diseases, passed the Senate

Senate Int. 588—For licensing school psychiatrists, etc., third reading

Senate Int. 807—Pharmacy, revoking licenses, third reading

Senate Int. 619—Motor fuel tax, to Governor

Senate Int. 620—Motor fuel, additional tax, to Governor

Senate Int. 706—Extending TERA, to Governor

Assembly Int. 123—Blood-grouping tests, reported

Assembly Int. 166—Blood-grouping tests, reported

Assembly Int. 194—Protection of water supplies, reported

Assembly Int. 196—Infectious diseases, reports, reported
 Assembly Int. 199—Employ dentists and health nurses, reported
 Assembly Int. 461—Clinical laboratory bill (including x-ray labys.), reported
 Assembly Int. 498—Grants and gifts to hospitals, to Governor
 Assembly Int. 763—Powers of local health boards, reported
 Assembly Int. 978—Mental institutions, purchase of supplies, reported
 Assembly Int. 1321—Blood-grouping tests, reported

HEARINGS

Feb. 26—As. Int. 578	{ Workmen's compensation, insolvent carriers; hearing before Assembly Committee on Insurance.
As. Int. 202	{ Civil Service Law, applicants, examinations; hearing before Assembly Committee on Judiciary.
Feb. 27—Sen. Int. 616 Sen. Int. 961	{ Exemptions, jury duty; hearing before Senate Committee on Judiciary.
As. Int. 150	{ Workmen's Compensation Law, physical examination of employees; hearing before Assembly Committee on Labor and Industries.
As. Int. 210	{ (Same as As. Int. 150.)
As. Int. 644	{ Occupational diseases, silicosis, etc.; hearing before Assembly Committee on Labor and Industries.
As. Int. 740	{ Workmen's Compensation Law, appearances of attorneys; hearing before Assembly Committee on Labor and Industries.

SPECIAL BULLETIN, FEBRUARY 28, 1935

Medical Abuses Bill Passed Out By Committee. The Medical Abuses Bill, Senate Int. 19, Print 774, has been passed out by the Senate Committee and is now on third reading. *We urge you to communicate with your Senator urging his support of the bill.* In mentioning it call it Senate Print 774,

N. A. O'Brien, Medical Abuses. Either wire, telephone, or write a letter. The bill probably will be voted upon Monday night.

The following resolution was introduced in the Senate yesterday. It asks for the appointment of a commission to study the administration of the Workmen's Compensation Law. *Read it carefully;* it is so far-reaching, that every physician ought to be familiar with what it contemplates:

RESOLUTION IN SENATE

By Mr. McNaboe: WHEREAS, by Chapter 41 of the laws of 1914, the Legislature created a fund to be known as "the State Insurance Fund" for the purpose of insuring employers against liability under the Workmen's Compensation Law; and

WHEREAS, Section 95 of the Workmen's Compensation Law provides that premiums in the State Fund shall be fixed at the lowest possible rates consistent with the maintenance of a solvent fund and of reasonable reserves and surplus; and

WHEREAS, Three bills are now before the Legislature for its consideration affecting the Workmen's Compensation Law, as now in force and effect, the first one, being Senate bill introductory number 18, giving to the State Insurance fund a monopoly in such compensation insurance; the second, being Senate bill introductory number 19, giving control of the practice of industrial medicine and surgery to the State and County Medical Societies; and the third, being Senate bill introductory number 20, enlarging scope of the coverage of compensable injuries; and

WHEREAS, It is charged, in respect of the State Insurance Fund, that the administration thereof is lax, corrupt, and inefficient; that its cases are improperly and inadequately investigated and prepared thus necessitating a greater number of hearings than should be required and thereby increasing the cost of administration and unduly delaying relief and compensation to the injured workman and causing the workman to attend unnecessary hearings; that its cases are unnecessarily fought strenuously and that but few cases are paid without controversy; that payment of its just medical and other bills is unjustifiably delayed from one to three years; that its doctors are employed largely through political favoritism and influence rather than because of their professional ability and standing; that doctors employed by such fund and others rendering service and supplies to the fund are compelled to split their fees with State officials; that doctors of mediocre or little ability are, as a result, given the medical work of such fund and that few men of outstanding ability and standing are employed; that hospitals are largely designated by such fund because of political influence and favoritism and not because of professional standing and merit; that the fund is inhumanely administered and payments to injured workmen unduly and improperly withheld and delayed to the great detriment of such workmen; that unfair discrimination in the law now exists in favor of the fund and against the private carriers in that the fund is permitted to rate up risks and the private carriers are not; that the statutory mandate to maintain a solvent fund with reasonable reserves and supplies is not being observed; that the fund is in fact insolvent; that the Industrial Commissioner has

unofficially conceded that the administration of the fund is far from what it should be; and

WHEREAS, It is charged that the State and County Medical Societies have failed to promptly and adequately discipline the members of the medical profession under the powers vested in them by the Education Law and weed out incompetent, unethical, and dishonest members of the medical profession; that a former Medical Director, Workmen's Compensation Division, Civil Works Administration, in a recent public article charged that the County medical societies in supplying him in his official capacity with approved lists of doctors for such work named "a large number of men not able and not ethical," a number sufficiently large to make him question the value of the County medical societies' estimate of their members and non-members as to capability and honesty; that the standards and qualifications required in this State as a condition to obtaining a license to practice medicine are not sufficiently high to prevent incompetent and unethical men from being admitted to such practice; that fee-splitting and its consequent and concomitant evils of unnecessary operations, treatments, the purchase of unnecessary surgical appliances, has become a common practice in the medical profession to the grave detriment and danger of the health and life of our people; and

WHEREAS, It is charged that the County medical societies are not truly representative of the medical profession but are, in the main, in the control of a few selfish, self-seeking members of the medical profession who wrongfully abuse such positions of honor and trust to and in their own interest and against the best interests of the medical profession and the public; and

WHEREAS, One of the primary objects of the State is to protect and safeguard the life and health of its people, and since the conditions recited hereinabove affect the health and welfare of the public as a whole and in particular the health and welfare of the injured workmen, the Legislature should be fully and adequately advised in the premises and in the adequacy of the powers of the Superintendent of Insurance under existing laws to efficiently and properly regulate and supervise private carriers of compensation insurance in order that effective and proper remedial legislation may be intelligently framed and enacted into law; now, therefore, be it

Resolved (if the Assembly concur), That a joint legislative Committee be and hereby is constituted to consist of four members of the Senate to be appointed by the Temporary President of the Senate and three members of the Assembly to be appointed by the Speaker of the Assembly with full power and authority to investigate, inquire into, and make a thorough and careful examination and investigation in respect of the operation and administration and costs of the State Insurance Fund in all respects and in every branch and department thereof including, but without limiting the foregoing, its financial condition, its solvency, and whether or not reasonable reserves and surplus are maintained by such fund as required by law, and including, but without limiting the foregoing, the investigation, preparation, handling, and payment of claims made against such fund and the selection, fitness, and conduct of its hospitals, its outside personnel and medical staff, and its purchases of supplies and surgical appliances and apparatus; whether or

not fees are given to or split with State officials as a condition to or as an inducement of employment or purchase by such fund; the practices of the State and County Medical Societies in general and in every respect and in particular in disciplining or failure to discipline, punish, and weed out incompetent, dishonest, and unethical members of the medical profession; of the adequacy and effectiveness of the present standards and qualifications required as a condition to practice medicine; of the practice of fee splitting among doctors, of operations without proper justification and of requiring the purchase of unnecessary surgical appliances; of the adequacy and effectiveness of the powers of the Superintendent of Insurance under existing laws to properly supervise and regulate the private carriers of compensation insurance, and into every matter and thing whatsoever connected therewith or relating thereto, or to any part of the foregoing directly or indirectly, including the past or present unlawful or improper influence, control and/or domination by any past or present public official or any past or present employee of this State or of any political subdivision thereof over in connection with the State Insurance Fund and its various operations and activities.

The investigation of such committee may include every matter and thing not specifically mentioned in this resolution deemed by the committee competent, relevant, and material in the ascertainment of the true situation respecting the matters referred to herein or directly or remotely connected therewith, as though specific provision and authority therefor had been expressly granted herein, and it may include a full and complete inquiry into every private carrier of compensation insurance.

That such committee be and is hereby authorized to sit in public or in private, in such place or places in the State of New York as it may determine to conduct the investigation herein contemplated and/or authorized or intended so to be during the present session, or, if deemed necessary by the committee, after the adjournment thereof with the same full power and authority such committee would or could have were the Legislature in session; to choose from among its members a chairman and a vice-chairman; to employ a secretary, counsel, accountants, and such other assistants as it may deem necessary; to subpoena witnesses, take testimony and compel the production of books, papers, documents, and other evidence, either public or private, deemed by the committee to appertain to or be connected with or bearing upon this investigation, either directly or indirectly; to have access to an examination by its members, counsel or employees, of all records, books, papers, and documents respecting the matters referred to herein or directly or remotely connected therewith, and otherwise to have all the power and authority of a committee of the Legislature.

The committee may, at any time and from time to time, by resolution of a majority of its members, be subdivided into sub-committees of such number as the committee may determine. Such sub-committees may sit, in public or in private, as they may determine at the same or different times and places in the State of New York. Such sub-committee shall have and possess all the powers and authority hereby conferred upon the committee as such, or to which it may be in any manner entitled.

The committee shall have full power and authority and it shall be its duty to prosecute its inquiry with all due speed in any and every direction and by any and every direction and by any and every means in its judgment to obtain full, true, accurate, and correct information in regard to and to speedily report upon matters contemplated by this resolution; and be it further

Resolved, That whenever in its judgment the public interest demands, the committee or sub-committee may determine that a person shall not be excused from attending and testifying before said committee or before any sub-committee thereof or from producing books, papers, and documents before the committee, or before such sub-committee in obedience to its subpoena on the ground that the testimony, or evidence, documentary or otherwise, required of him may tend to incriminate him or to subject him to a penalty or forfeiture; but no person so attending and testifying or producing such books, papers, or documents, who has duly claimed excuse or privilege, which would be sufficient except for this provision of this resolution and which said excuse or privilege has been expressly desired by the committee, shall be subjected to prosecution or to any penalty or forfeiture for or on account of the transaction, matter or thing concerning which he may as aforesaid testify or produce evidence, documentary or otherwise, before such committee or sub-committee in obedience to its subpoena; and be it further

Resolved, That the said committee shall report to the Legislature with all convenient speed, but not later than the first day of February, 1936, the results of its investigations, with legislative proposals which it recommends, and that such committee may also report from time to time such resolutions of its investigations as it may deem necessary for the action or advice of the Legislature; and be it further

Resolved, That the sum of \$100,000 or so much thereof as may be necessary be and hereby is appropriated from the contingent fund of the Legislature for the necessary expenses of such committee, to be paid out of the State Treasury on vouchers approved and audited according to law.

BULLETIN NO. 8, MARCH 1, 1935

The following bills have been introduced since the issuance of the last regular bulletin:

Senate Int. 1266, Byrne, adds new section to the Lien Law by providing for liens of hospitals, physicians, and nurses for care of persons injured as a result of negligence of other person or corporation. Referred to the Judiciary Committee.

Senate Int. 208, Byrne, the first hospital lien bill, was seriously attacked by the Bar Association on the ground that its enforcement provisions are entirely too weak. The bill was referred to the drafting room with the comment and this bill, 1266, is the outcome. Approved.

Senate Int. 1314, Esquirol; Assembly Int. 1616, Doyle, amends the Workmen's Compensation Law and the Education Law relative to care and treatment of injured workmen and for special licensing of physicians

to practice industrial medicine and surgery and for other purposes. Referred to the Labor Committee.

This bill was prepared by a representative of an insurance company. Its provisions in certain particulars are very different from those in Bill No. 19. It provides for special licensing by the Department of Education of those who would engage in compensation work and for the revoking of workmen's compensation license on charges after hearing. The bill also provides that no claim for medical or surgical treatment shall be valid unless within forty-eight hours following the first treatment the physician furnishes the employee, the employer, and the Industrial Commissioner a preliminary notice of the injury and treatment, and files a more complete report within twenty days; and the fees are to be subject to regulation by the board. It also provides for the transfer of patients: first, in the interests of the injured; second, if the physician does not possess a special license; and, third, "if he has not been licensed by the Education Department to treat the particular injury or condition existing."

Laboratories and bureaus engaged in x-ray diagnosis or therapy must be in charge of physicians specially licensed by the Education Department to handle industrial medicine or surgery. A physician wishing to engage in industrial medicine must "produce evidence of his training, qualifications, and equipment, and shall agree to limit his professional activities in connection with workmen's compensation cases to such medical care and service as his experience and training qualify him to render. He shall further agree to refrain from subsequently treating for remuneration, as a private patient, any person seeking medical treatment in connection with, or as a result of, any injury compensable under the workmen's compensation law, if his special license as provided in section twelve hundred fifty-nine-a of this chapter, has expired or has been cancelled, or if the person seeking such treatment was transferred from his care."

"The special license to practice industrial medicine or surgery, as provided in section twelve hundred fifty-nine-a of this chapter, may be revoked, suspended, or annulled, or the practitioner reprimanded or disciplined in accordance with the provisions and procedure of this chapter upon decision after due hearing of any of the following causes, in addition to those named in subdivision two of this section:

"(a) That the physician has been guilty of professional or other misconduct or incompetency in respect to medical services rendered in connection with the practice of industrial medicine or surgery, or

"(b) That the physician has exceeded the

limits of his professional competence in rendering medical care, as specified in the special license granted to him, or has made materially false statements concerning his qualifications in his application for such special license, or

"(c) That the physician has failed to submit full and truthful medical reports required to be made by him under the workmen's compensation law, to the employee, the employer, the insurance carrier or the industrial commissioner, or

"(d) That the physician has offered to or has participated in the division, transference, assignment, rebating, splitting, or refunding of a fee for medical care other than with a like specially licensed physician, in any case involving industrial medicine or surgery, or

"(e) That the physician has solicited, or has employed another to solicit for himself or for another the professional treatment, examination or care of an injured employee in connection with any claim under the workmen's compensation law.

"Immediately upon the expiration, revocation, suspension, or annulment of the special license issued to a physician to practice industrial medicine or surgery, the department shall publish the fact and remove the name of such physician from the list as provided for in section twelve hundred and fifty-nine a of this chapter"

Senate Int 1365, Thompson, Assembly Int 1688, Hall, amends the General Municipal Law, authorizing governing board of any county, town city or village establishing a public general hospital to acquire lands or rights or construct additional buildings for improvement or maintenance of such hospital. Referred to the Cities Committee

This bill is intended to meet certain specific conditions connected with a hospital in Senator Thompson's district

Senate Int 1374, Crawford, appropriates \$27,000 to increase supervisory service in State Education Department to develop more satisfactory preventive and corrective physical education and recreation programs for children and adults. Referred to the Finance Committee.

This bill emanates from the bureau of physical education in the Department of Education. It provides an appropriation for the institution in the public schools of additional physical corrective programs. The bill was before the Legislature last year

Senate Int 1413, Schwartzwald, Assembly Int 1776 Lo Re amends the Education Law making compulsory transportation and education of physically handicapped children, such children to mean children certified by State or local health boards or medical board of a board of education, as blind cardiopathic, crippled deaf, epileptic, tubercular, or otherwise so afflicted as to be in need of transportation and instruction. Referred to the Education Committee

We do not know the source of this bill, but

presume that it has come from some communities where transportation facilities for this type of children are not provided. The larger cities all have such provision, but they are lacking in many of the smaller communities of the State, yet the Education Law demands that provision shall be made for giving these children an education

Senate Int 1414, Schwartzwald, Assembly Int 1861, Lo Re, amends the Education Law relative to the practice of podiatry. Referred to the Education Committee

This bill provides for a separate examining board in the Department of Education

Senate Int 1415, Schwartzwald, Assembly Int 1862, Lo Re, adds new section to the Education Law, changing name of the Podiatric Society of the State of New York to the Podiatry Society of the State of New York. Referred to the Education Committee

Senate Int 1465, Coughlin, amends the Agriculture and Markets Law by providing when commissioner decides that carcass of cattle or part thereof, which reacted to tuberculin test, may be used for human consumption, he shall issue an order, all such cattle, however, to be slaughtered in abattoir under supervision of U S animal industry bureau. Referred to the Agriculture Committee

Assembly Int 1633, FitzGerald, amends the Public Service Law by providing nothing in law shall be taken to prohibit any water-works corporations from furnishing water to certain religious charitable, and benevolent corporations and societies. Referred to the Public Service Committee.

The objective from our point of view is to free hospitals from prying water tax

Assembly Int 1635, FitzGerald adds new section to the Conservation Law prohibiting after December 1 1936 the running into waters of State of sludge, acid, or refuse from oil works sugar houses or other factories, sewage or other substance injurious to human health or shellfish culture or fish and which may affect their flavor, odor, or sanitary conditions. Referred to the Conservation Committee

Assembly Int 1649, Burke, General Municipal Law, for formation of pest abatement districts on petition to Supreme Court of 100 or more voters cost to be assessed on properties benefitted for appointment of commissioners for each district on recommendation of Education Commissioner, who shall designate technicians from appropriate State departments to determine whether project is sound or desirable. Referred to the Cities Committee

Mr Burke comes from Queens County where there still are some swamps which breed mosquitoes. They have found it impossible to secure co operation from Greater New York in having the places eradicated. Suffolk and Nassau Counties both have active mosquito extermination commissions with appropriations

Assembly Int 1799, Heck, Workmen's

Compensation Law, providing workmen's compensation allowances in work relief disability cases. Referred to the Relief and Welfare Committee.

Last year the law provided that a special fund be created by the Temporary Emergency Relief Administration to guarantee persons injured or disabled while so employed, protection similar to that provided employees by the Workmen's Compensation Law. Mr. Heck's object is to transfer them to the one fund.

Assembly Int. 1863, McDermott, amends the Penal Law by providing experiments shall not be made upon a living dog. Referred to Codes Committee.

Our perennial dog bill.

PRIVATE AMBULANCE RIDERS

A 500-pound woman who fell out of the bed and needed help to get back; a rain-bound inebriate who couldn't find a taxicab; a Park Avenue whose Pekingese was in critical condition with distemper, and innumerable celebrities such as William H. Woodin, Marie Dressler, Anthony J. Drexel, and Colonel H. H. Rogers were among those who contributed in 1934 to an 8 per cent increase in the use of private ambulances throughout the New York metropolitan area.

Of last year's 21,000 calls, a larger percentage than ever before were to return from hospital to home patients just starting on the road to recovery. These moves varied in length from a trip across a West Side street to a 380-mile journey from Manhattan to Boothbay Harbor, Maine.

Private ambulances in operation in the city during the year traveled an approximate total of 600,000 miles. The Ghetto on the lower East Side competed with the fashionable upper East Side as the district from which most calls came.

January, February, and March led in the number of calls, probably because pneumonia is the disease from which the largest percentage of the patients were suffering. In July and August the calls were least. The evening dinner hour continued as the time of day when the demand for private ambulances was greatest.

The crippling effects of disease and accident are being reduced steadily in upstate New York through the work of the Division of Orthopedics, State Department of Health, allied agencies, and the various convalescent homes and hospitals caring for physically handicapped children.

A case in point is that of a young man, age twenty, who was discharged a year ago from a local hospital with the prognosis "wheel chair for the rest of life." Today he is playing basketball. The New York State Reconstruction Home at West Haverstraw is credited in part with his improvement.

Current Comment

Vernon A. Chapman, writing in the February issue of the *Medical Record*, says "the multiple economic troubles which now beset the members of the medical profession have been brought down upon their heads by the generosity, heedlessness, superiority complex, greediness and medical politics of the medical profession itself, and by the selfishness of its individual members. Employees of city, County, State or United States receiving salary for their work should employ and pay physicians in private practice for medical and surgical services they receive."

Last minute movements in reform are often instituted in efforts to escape retribution following reprehensible conduct."

Seymour Fiske, secretary of the Physicians Equity Association of America, Inc. says "In this fight to improve the economic condition of the doctors, the co-operation of all physicians is necessary."

The question of sterilization among humans who are classified as the "unfit" is receiving serious attention in many places. In the Philippine Islands, Dr. Lee S. Huizenga, speaking of its use among the lepers states "Sterilization of leprosy couples meets with many practical difficulties, at least for the present, and the supposed good to be derived is of a very questionable nature."

March 30 marks the eight hundredth anniversary of the birth of Moses Maimonides philosopher, teacher, writer, jurist, scientist Rabbi, and court physician to the Sicilian leader, Saladin, the Great. "Teach thy tongue to say, 'I do not know,'" said this great teacher.

Dr. E. H. Crane of Inglewood, California, relates an example of Compulsory Health Insurance practice in England.

After returning from a trip, the English doctor found thirty six patients waiting for him. He disposed of them in little over an hour as follows. With a handful of prescriptions he called out, "All who have a cough, stand up!" A prescription was given to everyone who stood up. The others formed a line and marched past his desk. "What's the matter with you?" he asked each in turn. And, as each replied, he received a stock prescription from a pigeon-hole in the doctor's desk. (Reported in the February issue of *Medical Economics*) (Oh shades of the Commission on the Costs of Medical Care! What crimes are committed in thy name!—Ed.)

English Health Insurance like that imposed upon Germany was a political action, and was not prompted by any humanitarian ideology.

To spike the guns of the labor party and add to his sources for voting power, Lloyd George imposed it upon England.

There is widespread sentiment in Great Britain toward complete state medicine and away from the present system of health insurance which embraces only 39 per cent of the population—(*Medical Economics* February, 1935, page 27)

There was a time not so far distant when medical economics and organized medicine did not travel exactly parallel paths. The ringing words of its editor H. Sheridan Brackett, are all the more noteworthy "So vast and all encompassing a project as national health insurance should be written into the laws of the country only after exhaustive criticism of its every detail. Appraisal of the issue should be based not on theory but on practical consideration. Disregard of this principle will lead the medical profession and the country at large into a first-class disaster."

"It is sheer folly to assume that subsidized medicine can be adapted as an 'experiment'."

Once committed to it, withdrawal will be impossible."

People have a natural tendency to belittle current events. Not until years—often decades—after a significant change has taken place, do they awaken to its full purport. Let the profession realize that at this very moment medical history is in the making. If the trend of coming events is to be altered, it must be altered now.

Small effort is required to change the course of a stream near its source. Superhuman efforts alone can divert the sweep of a river at flood.

A complete revision of the health program of the public schools of the whole state is foreseen, as the result of plans now under way. In the first place, under the direction of Dr. Franklin Smiley who has been inducted as Director of Health and Physical Education, the Board of Regents will inaugurate an effort to improve the school children's health. In the second place, Dr. H. F. Mace, A. Bauer, Miss Mary G. McCormick, and Miss Marie E. Swanson are holding a series of conferences with school principals and superintendents to cover a gap found among high school graduates in health education,

and adequate preparation for the latter problems of life. The school physicians of the State are also to receive a series of instructive lectures from Dr. W. P. Brown of the Medical Service Bureau.

"Our 'Biggest Health Program' facing the Department of Health is the medical and educational drive to eliminate venereal disease," said Health Commissioner John L. Rice of New York City. The program contains two main elements. First, every infected person should take treatment immediately; and second, facilities for the diagnosis and treatment of syphilis and gonorrhea must be available.

Dr. John A. Hartwell, Director of the New York Academy of Medicine spoke before the New School of Social Research on February 25, and chided the organized profession on its conservatism and its stand. He said the profession has been controlled "by fear and obstinacy." While Dr. Hartwell is Director of the New York Academy of Medicine, and as such, it is difficult to keep his utterances individual and not have them accepted as representative of the New York Academy of Medicine, yet the organized profession must bear in mind that Dr. Hartwell speaks for himself only. In justice to the Academy, let it be known that that educational institution

has taken no official position on the matters on which Dr. Hartwell talked. Fear and obstinacy indeed! It would be the easier way for the profession. to accept what is offered.

Organized medicine is not yet prepared to accept a ready made pattern of medical practice imported from abroad. It desires to safeguard quality of medical service, save patient-doctor relationship, reduce lay supervision and political control to a minimum, and at least give the public as good a service as the indigent now receive. Incidentally, it desires that these who enter this kind of medical practice shall have a livelihood from it, because private practice cannot be maintained along with this type of medical work.

Catharine Stoddard of Grosse Pointe Park, Michigan, asks a very pertinent question in *Medical Economics* (February issue): "So far, none of these critics [of the profession] has explained how the ethical tone of the profession will be improved, or the public better served by delivering the medical system into the hands of politicians. No one has yet offered any convincing evidence that government medicine burdened with huge administrative corps and affording innumerable opportunities for graft would be any cheaper for the average taxpaying citizen than private practice."

New Health Strategy in Northern Counties

Dr. Burke Diefendorf and a corps of assistants have occupied a new suite of offices in Ticonderoga, to have charge of state public health work in Warren, Washington, Essex, Clinton and Franklin Counties and also the towns of Long Lake and Indian Lake in Hamilton County.

Dr. Diefendorf will be assigned an assistant district state health officer, an assistant district state supervising nurse, a sanitary engineer, a milk sanitarian, and two additional nurses for Essex County and three additional nurses in Clinton County.

The major purpose of the nursing program is to acquaint the people with public health problems, especially those dealing with prenatal work, communicable diseases, control of tuberculosis, and in endeavoring to contact patients while in the early stages so that control may be had without necessitating hospitalization, also education programs in social health hygiene.

The clinic will be arranged as a demonstration, and not as a service project, to get in

closer contact with the average practitioner; this will tend to educate the public to the necessity of consulting their physician.

It is expected that tuberculosis clinics will be held in the several counties instead of conveying the patients several miles to one so-called centrally located clinic and the operation of these clinics will be from Ray Brook instead of Albany as heretofore.

The primary object of the State is to decentralize and bring the field workers into closer contact with the field operations. These nurses were sent to this northern section because it was felt that there was a greater need for them in Essex and Clinton Counties at present than in some other parts of the State.

This plan is to supplement the county health work with no added expense to the localities.

The additional nurses are part of the nationwide United States Public Health service program. This service continues for six months.

In order to promote the immunization of children against diphtheria in very young children, the New York City Department of Health will urge parents to have this treat-

ment administered as soon as the child is six months of age. Heretofore all the Department's leaflets and other announcements have advocated the ninth month.

County Societies

Cattaraugus County

Dr. R. M. Atwater, Cattaraugus County Health Commissioner, has resigned to become executive-secretary of the American Public Health Association at the Rockefeller Center in New York City.

Chemung County

Meeting of the Chemung County Medical Society was held January 30, in the library of the Arnot Ogden Memorial Hospital. Dr. LaRue Colegrove presided.

Dr. Colegrove opened the meeting with an expression of appreciation to the Society for electing him President for the fourth time since he became a member of the Society. Following this the Secretary read the minutes of the previous meeting which were approved and accepted. Secretary also read a letter from Dr. Colegrove to the Governor of New York State and Members of the Legislature, expressing the action of this Society as taken at a special meeting, January 16, in regard to the proposed State Insurance Fund. Dr. Colegrove then announced the Committee appointments for 1935 as follows:

Censors: Dr. Alfred J. Westlake, Dr. Charles Erway, and Dr. Alexander Mark.

Delegates: Dr. Reeve B. Howland and Dr. J. Lee Kinner (alternate).

Public Relations and Economics: Dr. Arthur W. Booth (chairman), Dr. John F. Lynch (vice-chairman), Dr. Leon Hamilton, Dr. Donald Tillou, Dr. Herbert W. Fudge.

Legislative: Dr. Elliot T. Bush (chairman), Dr. C. L. Leet, Dr. J. Lee Kinner.

Grievance: Dr. Ross Loop (chairman), Dr. John A. Bennett, Dr. S. L. Larson, Dr. F. E. Woodhouse, Dr. Arthur Glover, Dr. C. G. Zimmerman, Dr. W. T. Boland.

Public Health: Dr. Reeve B. Howland (chairman), Dr. Stewart S. Piper, Dr. Anna M. Stuart.

Postgraduate: Dr. Joseph Lewis (chairman), Dr. A. C. Smith, Dr. E. F. Butler.

Outing: Dr. R. A. Turnbull (chairman), Dr. Charles Haase, Dr. R. O. Gregory.

There were no committee reports and no business to come before the Society. The first speaker of the evening, Dr. W. P. Brown, of the School Inspection Bureau of the State Department of Health, gave a paper on the ideals of the School Medical Inspection Bureau. He pointed out that irrespective of remuneration, in order to give a reasonably good physical examination, it takes time. He believes that if the doctor doing school examinations would give an adequate amount of time to the individual

case, the standards of remuneration would be increased. He felt that the State Department, could in the future, promise to raise standards of pay. He pointed out also, that the school physician's main interest was in the prevention of disease and in bringing to the attention of the parents and the child's doctor the presence of defects at time of examination. He also told of the relationship of the school physician to the child's doctor, and pointed out that they could be of mutual benefit to the other. He begged for a more kindly understanding on the part of the general practitioner of the purpose of the school medical system. Following the paper Drs. Elston, Fudge, Voorhees, Howland, and Murphy took part in the discussion, and brought out specific points which could improve these relations.

The next speaker of the evening, Dr. Arthur W. Booth, of Elmira, spoke on what the A.M.A. is doing for the general practitioner. As a trustee of this organization, Dr. Booth is cognizant of any details of organization with which the average practitioner is not familiar. His paper showed the detailed activity that is going on continually to aid or to combat the practitioner. He pointed out the work the A.M.A. is doing to aid the public and various business organizations in the matter of better medicine. He stressed the great many items which the A.M.A. has to offer us in helping our individual practice, as well as the practice of medicine in general.

Members present were: Drs. Booth, Butler, Bleyer, Brequet, Colegrove, Cohen, Creighton, Dale, Davis, Dreyfuss, Erway, Elston, Fudge, Glover, Howland, Impert, Kinner, Loop, Leet, Lewis, Monroe, Maynard, Murphy, Smith, Stevens, Torrance, Turner, Voorhees, Westlake, and Zimmerman.

Erie County

Dr. Timothy F. Donovan, of Buffalo, died in New York City on January 31 of pneumonia, following an operation for ulcers at the Medical Center. He was 50 years of age, and was a brother of Col. William J. Donovan.

When America entered the World War in 1917, Dr. Donovan was among the first to offer his services. He relinquished a thriving private practice to accept an appointment as surgeon in the Medical Corps. He saw grinding service in the Argonne-Meuse and Alsace-Lorraine sectors. Promoted to the rank of captain, he continued overseas service until May, 1919.

Returning to the United States he devoted himself to surgery, accepting a post as in-

structor in surgery at the University of Buffalo.

At this time he was also associate attending surgeon to the three city hospitals. Dr. Donovan was a member of the A.M.A., New York State Medical Society, Erie County Medical Society, Buffalo Academy of Medicine, Omega Kappa Psi, Phi Kappi Psi, Buffalo Club, Saturn Club, Buffalo Tennis and Squash Club, Columbia University Club. He attended New St. Joseph's Cathedral.

Nassau County

The Professional Advisory Committee of the Medical Society of the County of Nassau has investigated the charges made in Freeport newspapers that a few doctors have been getting more than half of the medical relief funds, and the rest little or nothing. The committee has "studied carefully" the newspaper articles, it reports, but except for "the fact that certain doctors received what would seem to be an unreasonably large share of the funds, there is nothing in them to prove that these fees have not been earned." The committee finds "three locations in the county where the welfare work has been concentrated in the hands of a limited few doctors," and "there has been evidence that this work has been 'steered' in some cases," much of it over a year ago. A few doctors "writing unnecessary prescriptions" have been "warned that further transgression will result in their being removed from the list of those entitled to do welfare work." Others, "suspected of making unnecessary calls," have also been warned. "As a whole, however, the skirts of the medical profession have been clean. Of the approximately 360 doctors in the county, less than a dozen have been under any sort of suspicion, and some of those have been exonerated." The *Nassau Review*, the newspaper publishing the articles, is told that if it "has evidence that a single dollar has been paid to a physician in this county for work that he did not do, or if the *Review* has any evidence that a single physician has been 'buying' welfare work, the facts should be reported, preferably to the district attorney," and "if anyone has evidence that other irregularities exist they should be reported to the relief bureau or to the professional advisory committee. It must be remembered that backyard gossip and current rumor are not evidence and it is extremely difficult to correct an unsatisfactory condition unless full facts are known."

New York County

A conference on medical problems of the next war was held on February 6 at the New York Academy of Medicine, under the auspices of the Harlem Medical Association. The main subject was the problem of defense

against gas attacks. Incidentally Dr. Albert S. Hyman, president of the Association, revealed that the several hundred physicians and officers present had almost themselves become the victims of a surreptitious gas attack.

Some men carrying stench bombs were caught as they were about to plant them in strategic places in the building, Dr. Hyman revealed. They were ejected before they could carry out their plan, he said.

A number of unknown persons, however, had managed to distribute handbills demanding the abolition of war and urging physicians to join the League Against War and Fascism.

The *New York American*, in speaking of the address of Dr. William P. Murphy at the dinner of the New York Dietetic Association on February 8, referred to him as "Winner of the Hotel Prize in Medicine."

Onondaga County

Dr. George C. Ruhland, Syracuse health commissioner, has resigned to become health director of the District of Columbia. The Mayor said in an interview that "Syracuse has reason to be proud that its health record was so outstanding that Dr. Ruhland should have been sought for this important post in the official home of our President and Congress." Dr. Ruhland was director of the well-known Syracuse health demonstration, financed partly by the Milbank Fund. Under his guidance, the city has risen to rank among the 10 most healthful in the United States. Prof. Winslow of Yale estimates that with the saving of lives from the acute communicable diseases, the reduction in infant mortality and the prevention of deaths from tuberculosis during the last decade, in Syracuse, the economic value of these lives saved is approximately \$3,500,000 a year.

Queens County

Dr. Luther Fiske Warren, professor of medicine at Long Island College of Medicine, advocates the formation of a Health Council, representing all important health agencies and sponsored by the Chamber of Commerce, as the first step in an effective preventive and remedial health program for Queens.

He spoke at the second of a series of forums on "What Queens Needs," arranged by the Queensboro Council of Social Agencies and sponsored by leading civic, professional and social organizations of the borough, on February 6.

The meeting was held at P. S. 20.

Schenectady County

Dr. William Paul Brown addressed the Schenectady County Medical Society on

February 6 on "The Physician and School Health." In his report he said:

"Very informative surveys by the State Education Department show a neglect of health procedures for school and preschool youngsters. Over-tiredness is evident in 42 per cent of average children, in a study of 3,512 pupils. The foods were not proper for a large majority, and this error was made worse by the almost daily eating of candy between meals. Candy is somewhat of a food, but it is added to a diet already twice as sweet as that of any other nation, and it is often taken just before meals. Parents seem not to have training for their job, and it almost looks as if we should train all pupils for the job of parenthood while they are still in school. Dental disease is very prevalent, echoing the unbalanced foods of younger years. Early repair of teeth is surprisingly postponed. Retardation of learning is found a complication from under par condition of health.

"Twenty per cent are getting little or no milk. One-quarter of the children receive insufficient vegetables. Two-thirds are addicted to unnecessary use of laxatives. Mental abnormalities are in need of guidance,

and are a proper function of the doctor. It is apparent that the heads of families are not managing the aspects of health behavior in a reasonable degree. The family physician has a distinct function in assisting the parent in the choice of health conduct to be promoted."

Warren County

The annual meeting of the Warren County Medical Society was held at Glens Falls, January 9, 1935. The following officers were elected for the ensuing year: Dr. Leonard Hulsebosch, Glens Falls, president; Dr. George Bibby, Pottersville, vice-president; Dr. Morris Maslon, Glens Falls, secretary-treasurer.

Dr. Frederick E. Elliott, chairman of the Committee on Economics, of the Medical Society of the State of New York, addressed the Warren County Medical Society on "Current Events in Medical Economics." Dr. William P. Brown, State Education Department, spoke on "The Physician and School Health."

Drs. John E. Cunningham, Warrensburg, and H. H. Dier, Lake George were elected members of the Society.

Medicolegal

LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

Plaintiff's Burden of Proof in Malpractice Action

A malpractice case* recently decided upon appeal in one of the New England States presents an interesting situation for comment in these columns.

After having undergone certain treatment at the hands of a certain doctor, the plaintiff, charging him with negligence, instituted an action to recover damages for personal injuries which he alleged were caused by the malpractice of the doctor. Before the case was reached for trial, the doctor died. Under the laws of the State in question the defense of the case was continued by the doctor's administrator, so that upon the trial the defense was naturally at a considerable disadvantage.

Upon the trial of the action, it appeared from the testimony that the doctor, whom we shall refer to as the defendant, had performed an operation upon the plaintiff, and had removed a hard growth from the underside of the upper eyelid of plaintiff's right eye, which was described as a chalazion. Previously several similar growths had been

removed from the patient's eyelids by other doctors. Three of them had affected the right eye and one had been on the upper lid of that eye. According to the plaintiff, the defendant had rolled back the eyelid, held it with a clip, applied a local anesthetic and cut out the growth, and curetted. Up to that point of the operation the patient had felt but little pain. He said that the defendant had then applied to the eye from a bottle, some drops which caused severe pain and a burning sensation. At this point it was claimed that the doctor started trembling, and had wiped out the eye and applied another substance. The patient was given some drops to take home with him for application to the eye.

The testimony showed that the defendant treated the patient for four days after the operation. The patient then entered a hospital for treatment. The diagnosis on admission was "traumatic keratitis" which was defined as inflammation to the cornea due to a wound or injury. The records showed that a large ulcerative area was present, which involved almost the entire cornea; and that a further

* *Semerjian v. Stetson*, 284 Mass. 510.

diagnosis of "ulcerative keratitis" was made. Upon the trial the plaintiff testified that the sight of his right eye was practically gone.

The plaintiff also testified that before the operation he had had a discussion with the defendant about the fact that there was no assistant present during the treatment. He testified to conversations with the defendant about the application of a "caustic" to the eye, and to conversations afterwards in which he had accused the defendant of ruining his eye, and his life and business. The plaintiff asserted that the defendant had replied, "Don't you worry. Let me worry," and that the defendant had told him he was delaying further treatment waiting for a different medicine to arrive from some other city. The defendant, he said, had also told him on one occasion that he was unable to do anything for him other than he had been doing, and gave the patient a letter addressed to a doctor at the hospital where he subsequently received care.

Upon the trial the plaintiff did not put any doctor upon the stand as an expert to establish that the defendant had failed to conform with proper standards of care or to establish a causal relation between the claimed negligence and the injury. He contended that the testimony above referred to constituted sufficient evidence to show admissions of negligence by the defendant. At the close of the plaintiff's evidence the defendant rested his case, putting no witnesses on the stand. Thereupon the trial court directed a verdict in favor of the defendant.

An appeal was taken, and the Appellate Court affirmed the ruling of the trial court. In its opinion, it said in part:

The question here presented is whether a jury would have been warranted by reasonable inference in concluding that negligence of the doctor in putting the drops in the plaintiff's eye was the cause of the conditions which appeared after the operation. The permissible drawing of an inference by a jury is a process of reasoning whereby from facts admitted or established by the

evidence, including expert testimony, or from common knowledge and experience, a reasonable conclusion may be drawn that a further fact is established. There was here no expert evidence other than what appears in the hospital report. The mere fact that pain, inflammation, and an ulcer in the plaintiff's eye followed the operation did not justify the inference of want of proper care and skill on the part of the doctor or warrant the conclusion that these conditions were the result of the doctor's negligence. There was no evidence tending to show the source or constituent elements of the liquid put in the plaintiff's eye, the purposes for which it is commonly used, its ordinary effects and characteristics or that it was or was not in general use by doctors following or in connection with such operations upon eyelids. The mere fact that an unidentified liquid placed in an organ as sensitive as an eye was followed by pain and inflammation would not without other evidence warrant the inference by a jury that its use was improper. There was no evidence as to the character or extent of injury which might cause an ulcer in an eye; or as to the ordinary origin, characteristics, and development of such ulcers; or as to the causes which are commonly adequate to produce them. We are of the opinion that the record lacks elements which are essential before a reasonable inference can be drawn that negligence of the doctor caused the conditions appearing in the plaintiff's eye after the operation and that the common experience and knowledge of a jury of laymen cannot supply the lack. . . . The doctrine of *res ipsa loquitur* is not applicable whereas here the common knowledge or experience of men is not extensive enough to permit it to be said that the plaintiff's condition would not have existed except for negligence of the person charged.

It should be noted particularly in connection with this case that when the action came on for trial, the defendant doctor had passed away. Such a situation could not occur in New York, for in this State the law has been well settled for many years that actions for personal injuries abate with the death of the defendant, and it has been established that malpractice actions based upon claims of improper and unskillful treatment are included in the category of such actions for personal injuries.

MEAT AND STAMMERING?

An absence of meat in the diet of an infant or child may be a predisposing factor in causing stammering, according to Dr. Knight Dunlap, of the Department of Psychology, Johns Hopkins University. In a report of his findings in *Science*, Dr. Dunlap says that he has come to this conclusion from a study of childhood history of a number of stammerers who have come to him for treatment.

"From the age of two years, there is no reason why children should not have meat at least twice a day," Dr. Dunlap said. "In many cases where the diet has previously been badly managed, the problem may be to induce the child to eat a sufficient quantity.

Variety of meats and of preparation, with good psychological technic, offer the solution to this problem. Overcooked meats should probably be avoided." Whether a full meat diet would aid the adult stammerer is conjectural, Dr. Dunlap said.

"The situation of the adult stammerer is of course, quite different from that of the stammering child or adolescent," he said. "That which may have a predisposing cause in infancy may have other bearings in adult life. Since a surprisingly large number of adult stammerers are relative vegetarians, it would seem possible that meat diet would be advantageous to many of these cases."

**HEARING RECLAMATION AND PRESERVATION IN THE
MODERATELY DEAFENED CHILD****Management and Treatment Based on Ten Years
of Clinical and Laboratory Research****EDMUND PRINCE FOWLER, M D
NEW YORK CITY**

The term deafness is used very loosely. It may mean anything from a slight dullness of sensation to a total loss of sound perception. It is the author's custom to designate deafness or loss of hearing, or impairment of hearing as slight, moderate, severe, very severe, and total, and to think of these designations as approximately equivalent to the following losses in sensation units:

Slight Not over 20 SU* down from average normal

Moderate Over 20 to not over 40 SU down

Severe Over 40 to not over 60 SU down

Very severe Over 60 to the lower limit
Total When very loud sounds are felt, but not heard

(If desirable one may add "Extreme" for losses over 80 to the lower limit.) This nomenclature lends itself readily to the adverb forms slightly, moderately, and severely deafened, and so on.

Many persons with slight hearing losses (up to 20 SU) do not realize they are deafened until accurately tested, and their friends may not realize their deafness, especially if only one ear is subnormal. Even severe deafness may be present without realization by the subject or his comrades. In one school the author detected four children totally deaf in one ear, all of whom denied any deafness. All

this shows the necessity of scientifically testing school children before they begin their schooling and at regular yearly intervals thereafter.

The author is aware that a few otologists believe that there is no use in examining school children because "deafness in childhood from otitis media alone or accompanying bodily disease is self-limited, and largely tubotympanic in etiology, that treatment benefits little, and that otitis media never causes progressive deafness." He disagrees with these beliefs.

Severe bilateral deafness compels recognition and suggests efforts for alleviation and management, but moderate deafness is often not realized as a handicap or not realized as existing at all. Hence the severely deafened child often secures much attention both as to treatment and management, and the moderately deafened child little or none. Deafness on the average responds to treatment in an inverse ratio to its severity and chronicity, so that very severe deafness responds but little to treatment. But severe deafness is usually preceded by moderate or slight deafness, and deafness in one ear is often followed by deafness in the opposite ear. The author's experience shows that moderate and slight deafness may be and often is benefited, and potential and increasing deafness forestalled by proper management and treatment. It is his intention therefore, to discuss particularly the moderately deafened school child and to show the amount of handicap and the amount of relief that such a child may experience depending upon the failure or the success of management and treatment.

When, in order to hear a moderately

* A sensation unit (a decibel) is the minimum amount of change in loudness of a sound that can be sensed by the human ear. As loudness is sensed logarithmically a sensation unit (SU) at the threshold of hearing will represent a change much less than at intensities 10, 20, 30, 40, and so on, units above threshold. In fact the sensation scale as plotted upon the audiogram chart makes the units increase in the ratio of 10, 100, 1,000, 10,000 and so on.

loud sound, it is necessary to get nearer than is usual, deafness should be suspected, but the ordinary spoken voice and many teachers' voices are so loud, that it requires on the average a loss of 30 to 40 S.U. in hearing acuity before much inconvenience is experienced. As a matter of fact if a classroom is noisy and the teacher tends to speak very loudly, the moderately deafened pupils may be benefited by the noise, first because of the increased loudness of the teacher's voice, and second, because the disturbing sounds are less noticeable to the deafened than to the normal hearing pupils—i.e., the paracusis Willisiana phenomenon.

The author's investigations show that when the hearing of a child is down 30 S.U., it means that if this child is to hear as well as a normal pupil on the back seat of a 30-foot schoolroom, he must be moved to within approximately three or four feet from the teacher. And even then he will be at a disadvantage as compared with those on the back seat, because whenever the teacher moves away from her desk, the speaking distance will usually be increased. For normal hearing this makes but little difference because tests show that in "live rooms" the loudness of the voice does not vary much unless the hearer is within four feet of the speaker, but for defective hearing it is imperative that the speaking distance be maintained near four feet so that the intelligibility may remain above the threshold for adequate understanding.

When a child's hearing is down 40 S.U., it means that in this same 30-foot school room he must be placed within a foot or two of the teacher to make the latter's voice appear as loud as to the normal hearing children sitting 30 feet away. Of course, this does not mean that the deafened child cannot otherwise hear the teacher at all. It means that what he or she hears is fainter, indistinct, and often unintelligible, because words, letters, or phrases are missed. These distance requirements are usually impossible to satisfy, though the scholar be given a front seat, and so our efforts may be insufficient for the desired results. What then should be done for the deafened child and especially for the moderately deafened child?

The most important thing is to discover the presence of the hearing defect. This is best accomplished by routine group tests using the 4A audiometer. After screening out those with hearing losses of less than

9 S.U., one proceeds along the following lines:

First, a careful functional test and otological examination are made, with subsequent follow-up, not only for those showing defects in hearing but also for those with histories of or suggestions of past ear pathology. The latter are regularly ignored, but experience demonstrates many such will subsequently develop deafness, and that at least one in twenty will have otosclerosis with or without deafness.*

The accompanying form was devised for a survey of 600,000 school children now proceeding in New York City. This is one-half of the total public school pupils in the greater City.† This chart while not perfect from the broader otologic standpoint, will serve as a guide for school examinations, and if every item is taken up in turn and carefully gone into, not only will we have some worth while statistics, but at comparatively small expense of time and money the children will have obtained an examination far better than any heretofore obtained on a large scale, and not so regularly obtained even on a small scale. Space prevents detailed discussion, but the questions are largely self-explanatory. The answers to these, and the 2A audiogram charts are filled in by the teacher-technician or nurse. Some 300,000 histories and several thousand audiograms have been completed to date. Both A.C. and B.C. are tested, and charted with the same base line as the normal. This is the simplest and by far the most satisfactory method of charting the functional tests. It is the only way in which complete and accurate data can be quickly obtained to aid in diagnosis and to establish a record from which future changes in function may be estimated. No very satisfactory method of testing the preschool children in groups has as yet been discovered.

Especial notice should be paid to the

* "Otosclerosis Complicated by Other Lesions," *Ann Otol Rhin. & Laryngol* Vol 42, p 714

† This survey is the result of the constant efforts of the New York League for the Hard of Hearing, Inc., Mr. George Chatfield, and the co-operation of the District Superintendents. It was made possible by the aid of funds from the Department of Education and the C.W.A. Two hundred and eighty teachers were instructed in the teaching of lip reading, and in the use of the 4A and 2A audiometer by Miss Estelle E. Samuelson of The New York League for the Hard of Hearing, Inc.; Mr. Daniel Caplin, Assistant Director of Health Education, was in immediate charge of the project and the author's own efforts were concentrated upon the medical aspects, especially in training the otologists and teachers in the use of the chart and in obtaining co-operation from the New York Academy of Medicine and the various County Societies, and the Hospital Clinics and the otologists generally.

questions which are designed to bring out inflammatory etiological factors, the underlying cause of most of the acquired deafness of childhood; also to each item in the otoscopic examination, and under diagnosis the new term "Past Masked Otitis Media (purulent or nonpurulent)." This was coined to cover those cases giving no history of inflammatory otitis, and yet showing unmistakable signs of past trouble, such as healed or open perforations, scars, congestions, adhesions, retractions, diminished motion, and so on, of the membrana tympani, tensa or flaccida.

Second, one should insist that advice and treatment be carried out, as otherwise there will be little or nothing accomplished by the otological examination. The school otologist checks or inserts the diagnostic findings and indicates what treatment if any is advisable. If the private or clinic otologist disagrees with these findings or the advice, he writes his own opinions in the space provided for this purpose. By having both otologists commit themselves in writing it is hoped that both will be kept aware of one another's critical examination and data, and be more thorough than is usual. The greatest difficulty is to obtain proper advice and treatment for the non-surgical cases. These, as a rule, are treated with little consideration, and as has been stated before, 50 per cent of them could as well stay at home, since loss of time and often routine ill-advised catheterization, nose operations, douches, packs, and sprays may do them more harm than good. Prevention is of the utmost importance and should be stressed in every case.

The school otologists instructed in the use of this chart will have obtained an outline for careful work, which it is hoped will make a favorable impression, and perhaps serve as a wedge to penetrate into the do-nothing attitude of parents, teachers, many general practitioners, and even some otologists. To obtain quicker and more permanent results home treatment is often of service.

Third, one should insist upon lip reading, not only as an immediate aid to the hearing, but as a partial insurance against possible future increased deafness.

Fourth, a front seat is imperative, not only for better hearing but for better lip reading. In every school one or more teachers should be trained in the teaching of lip reading, and all teachers in properly using their lips in articulation. We are

now trying to do these things in New York. Presently the author will show the value of lip reading by actual measurements of the intelligibility of the teacher's spoken words.

Fifth, teachers should favor even the very moderately deafened children by clear enunciation and repetition and position, so that these children may simultaneously not only hear the teacher but clearly see her lips. Clear enunciation and a clear view of the lips is important not only for the deafened children, but for the majority of children with perfect hearing, because both otherwise may continue to mimic the often strange and distorted word sounds heard among their fellows and at home.

Sixth, a moderately deafened child should never be relegated to a special school for the hard of hearing. He or she should carry on in the regular classes. It is here that more normal development and adjustment will obtain.

The handicap of deafness, *per se*, is not the most cruel thing that happens to these children. The most cruel thing is the handicap of *never having been permitted* adequately to hear the common words and thoughts of others. This handicap due to faulty care often wrecks the child's life. It gives the little one an appearance of stupidity when really no stupidity exists, and because of limited vocabulary and inadequate expression and the impossibility of easy companionship, it engenders the psychological maladjustments peculiar to extreme deafness. This suffering is brought about largely because of thoughtless resistance to measures which appear to apply to but a small number of students (the severely deafened), but which really apply to many whose hearing by superficial standards may appear sufficient for ordinary needs. This suffering may be largely overcome by proper guidance. The moderately deafened and even the severely deafened should be able to go through lower, upper, and high school, and through college, if they receive attention in the ways indicated herein.

Seventh, if the maneuvers mentioned above do not adequately supplement the deficient hearing, the hearing must be increased by other aids, such as individual hearing devices or the microphone with ear-piece receiver. (The loudspeaker and large horns built into the students' desks have proved unsatisfactory.) With the aid of the Staff of the Bell Telephone

Laboratories* the author has tested in the classroom children with various degrees of deafness and submits herewith a résumé of some of the data obtained from those moderately deafened.

Twenty-five children were tested on March 3† and 22 children on April 28, 1934. The accompanying table shows the results from the 20 moderately deafened children tested on April 28, dividing them into 3 groups according to their hearing losses, and the average group intelligibilities obtained.

The results have further been condensed by averaging some of the data, first, from the air tests, second, from the lip reading tests, and third, from those hearing aid tests in which the caller was speaking toward the microphone and within three or four feet of it. When the caller was more than four feet from the microphone the hearing aid gave practically no consistent advantage to the observer. Average values for the individuals and for the observer groups are given in the accompanying chart, "Individual Audiograms and Average Results." For Groups 1 and 2 the data show rather small variation as between the different testing conditions. A few children show diametrically opposing results, which demonstrates the necessity of studying individual cases and of using average values. The conclusions obtained from these tests substantiate those obtained from the results on March 3, so that the following conclusions are based on all of the results obtained to date.

The first group (with hearing losses less than 30 S.U.) misses part of the oral work, but the advisability of using a hearing aid is doubtful. The increased intelligibility obtained when speaking numbers was so slight that no significance could be attached to it. The test made on March 3 indicated that the school set-up was an impediment when words were used, while the tests made on April 28 showed practically no change. This discrepancy is due to the greater efficiency of the hearing aid used in the second tests. A front seat and individual consideration appear to give greater satisfaction than a hearing aid alone.

The second group (with hearing losses more than 30 S.U. but less than 40) showed some who might be classed with the first

group and therefore will probably not receive much assistance from hearing aids, and some others who did so badly in the air tests (without any aids) that they would undoubtedly benefit from hearing aids, and might therefore be grouped with those having approximately 40 S.U. hearing losses. The second group is, therefore, the dividing group between those needing electrical aids and those not needing them for their class work. Each child will require individual trials to determine this point.

The third group (with hearing losses near 40 S.U.) showed every member missing part of the test material, whether words or numbers, and that the benefit derived from the hearing aid varied greatly as between individuals and also for the type of test material used. However, a very noticeable gain was obtained when the speaker was less than four feet away from the microphone. A circuit having approximately 20 d.b. loudness gain should be used and individuals with hearing losses greater than 35 S.U. who are not definitely helped by such an aid would be the exception rather than the rule. Since the results appear to be so much better when the teacher is near the microphone, one microphone should be placed near the teacher's desk and a second microphone located at some advantageous point along the blackboard—the latter to be brought into use when required by a switch used by the child.

Every group tested and practically every individual was aided by lip reading. The three or four students who had not received much special training showed a less definite gain than the others.

The audiogram chart allows one to visualize the hearing capacity of each child and the figures show the improvements under the varying tests. It also makes it clear that even among these moderately deafened children there are many who will have low intelligibility results in spite of lip reading and in spite of hearing aids.

Eighth, special schools for the very severely deafened, and for the moderately and severely deafened who lack sufficient knowledge of language to carry on in the regular classes, should be advised. As soon as these are capable of rejoining the regular classes they should do so.

Ninth, medical care is important when indicated. For the moderately deafened child it is always indicated in some meas-

* Tested in a classroom at the New York League for the Hard of Hearing, Inc.

† The March 3 data are omitted here because they concern more the severely deafened.

Tests 6 to 10 — Word tests with no lip reading. Hearing aid microphone hung over the desk.

Tests 11 to 13 — Word tests with lip reading and hearing aid, microphone hung over the desk.

Tests 14 to 15 — Number tests with no lip reading and no hearing aid.

Test 16 — Word test with no lip reading. Hearing aid microphone hung on blackboard.

Tests 17 to 19 — Word tests with no lip reading. Hearing aid microphone set on the desk.

CLINICAL ASPECTS OF FORCED PERIVASCULAR DRAINAGE OF THE CENTRAL NERVOUS SYSTEM

GEORGE M. RETAN, M.D.
SYRACUSE

In 1930 I treated a case of syphilitic meningitis in an infant six months of age. This infection had produced a progressive hydrocephalus. Vigorous anti-syphilitic treatment over a period of three months failed to produce any clinical or serological improvement. The prognosis under these circumstances being universally bad, I felt justified in using any clinical procedure that might have a prospect of success. I therefore decided to alter the osmotic pressure of the bloodstream by the intravenous injection of a hypotonic solution containing an arsenical; also coincidentally to drain the spinal fluid hoping that it might be possible to draw enough arsenic through the lesions of the central nervous system to produce a therapeutic effect. The therapeutic result of this experiment was both prompt and definite. In fact, after four such treatments the patient had apparently recovered and has developed normally since.

At that time I made a careful search of the medical literature and found that this type of treatment had never been used for the treatment of infections of the central nervous system in humans. One case of trypanamide amblyopia had been reported by Casten¹ in which this principle was used.

The development of the experimental background for this treatment may be traced through the work of Starling, of Weed and McKibbin, and of Kubie. Starling² in 1909 published his studies on the formation of lymph.

The essential facts which relate to the present subject ought to be reviewed. Osmotic equilibrium between the bloodstream and the perivascular fluid spaces of the body is maintained by the osmotic action of the non-diffusible colloids of the blood and the crystalloids. Outside the capillary wall the crystalloids are more concentrated than the crystalloids of the bloodstream. This tends to balance the action of the non-diffusible colloids. Fluid movement from the bloodstream is assisted by blood pressure in the arterial capillary. Passing through the arterial capillary to the venous

side, the non-diffusible colloids are able to withdraw fluid from the tissue spaces by the aid of turgor pressure.

There are other factors influencing these forces, such as, e.g., water of metabolism; the breaking up of particles into smaller molecules, thereby multiplying their osmotic force; and certain electrical charges, not well understood.

Weed and McKibbin³ in 1919 studied the effects of the injection of hypotonic solutions into the bloodstream of animals. They found that such solutions produce hydrosis of the pericellular fluid spaces in the brain and cord and widening of the perivascular fluid pathways.

In 1928, Kubie⁴ further demonstrated this phenomenon and found that when a needle is introduced into the subarachnoid space and the cerebrospinal fluid allowed to drain, no hydrosis of the brain or cord results either in gross or microscopic sections. Kubie's work allows for the clinical application of these principles to the treatment of infections of the central nervous system. He suggested the name "forced spinal drainage."

In developing this method of treatment in infections of the central nervous system in humans, I have met with considerable difficulty as a result of the term "forced spinal drainage." A number of doctors have assumed that drainage of the spinal fluid is the essential factor. It is therefore fitting to suggest "forced perivascular drainage" as a term which more accurately describes the essential factor involved.

Within the central nervous system is found, existing under a varying degree of pressure, a lake of fluid largely derived from the bloodstream by way of the choroid plexus. Within the bony confines of the skull and spine there are no lymphatics. Their function is taken over, in part by the Virchow-Robins perivascular spaces, which form drainage channels between the perineural fluid spaces and the subarachnoid space. Through these drainage channels products of cell metabolism are carried to the spinal fluid. To increase the

drainage from these perivascular spaces it is necessary, first, to reduce the intracranial pressure to atmospheric pressure, and, secondly, to provide an increase of pericellular fluid. The first is accomplished by lumbar puncture with continuous drainage of spinal fluid; the second by the injection of hypotonic solution into the bloodstream. In cases of infection of the central nervous system, both in experimental animals and in humans, it has been demonstrated repeatedly that by use of this method products of inflammation can be washed from the inflamed areas in the depths of the central nervous system to the subarachnoid space.⁶⁻⁹

In certain diseases of the central nervous system are found collars of round cells in the perivascular spaces. In poliomyelitis this type of pathological process affects wide areas. In acute encephalitis and in Sydenham's chorea it is limited to relatively small areas. Perivascular round-cell infiltration does not represent the only type of pathology found in these diseases. There are also found hemorrhages, edema, areas of softening and actual cell destruction.

A review of 115 forced perivascular drainage treatments shows the following results in regard to cellular behavior in the spinal fluid.

1. Patients without active infection of the central nervous system fail to show any cells in fractions of fluid examined during the intravenous injection of hypotonic solution. (See Table I.)

2. Patients with syphilis of the central nervous system, of many years' duration, and who have had years of anti-syphilitic treatment, also fail to show cell response. Similar results have been obtained in cases of chronic encephalitis of six and seven years' duration. (See Table II.)

3. In cases of septic meningitis there is a steady reduction in the number of cells found in fractions of the spinal fluid throughout the treatment. These cells continue to be practically 100 per cent polymorphonuclear leukocytes. (See Table III.)

4. In cases of acute poliomyelitis, during continuous drainage, and before the hypotonic solu-

tion is injected into the bloodstream, there is a reduction in the number of cells found in fractions of the spinal fluid. However, the relation between the percentage of polymorphs and lymphocytes in the spinal fluid is not greatly changed. If a hypotonic solution is then injected into the bloodstream there is a prompt increase in the number of cells found in fractions of the fluid with a shift to a preponderance of lymphocytes. (See Table IV.)

5. In cases of chorea, in which the cells in the spinal fluid are all lymphocytes, usually with a normal cell count, later fractions practically all contain lymphocytes, usually in increased numbers. However, certain fractions may contain no cells. These cases show in their later fractions a very small number of cells as compared to the later fractions in acute poliomyelitis. (See Table V.)

The various cellular responses of the spinal fluid mentioned above have been constant during forced drainage in all cases treated.

The cell behavior in the spinal fluid of the polio monkey does not follow the same pattern observed in the human disease. In the later fractions of the late disease in the monkey we find a higher shift to the polynuclear leukocytes than has been found in humans. (See Tables VI and VII.)

There is another principle of the greatest importance in considering this mechanism. It has to do with the movement of water from the bloodstream into the

pericellular tissue spaces in inflamed areas where there is increased permeability to fluids. If the osmotic pressure of the bloodstream be reduced by the injection of hypotonic solutions, the change in osmotic force will be largely exhibited at the point of least resistance which is the inflamed area. In case there is an active inflammation of the lungs, an edema of the lungs will occur almost as soon as the hypotonic solution enters the bloodstream. I have observed this in cases of latent tuberculosis and influenzal bronchitis. In several of my cases pyuria was present resulting in a copious excretion of urine. This materially interfered with the fluid passing through the central nervous system. In these cases no pus was found in the urine following the treatment. I have also observed in one case of tuberculosis meningitis with an acute colitis, a profuse excretion of water from the bowel during the intravenous injection.

Clinical research involving the use of a therapeutic procedure is difficult of interpretation. Evaluation of the subject at hand is further complicated by the wide variation possible in technical procedure. In addition, the responses of various clinical cases of the same disease are not comparable. Preventing paralysis in a case of

pre-paralytic poliomyelitis by a therapeutic agent may have no significance. Possible changes in the behavior of the patient may be significant to the physician who observes them. Poliomyelitis is not the most desirable disease in which to demonstrate various procedures, for fear of erroneous conclusions. This is equally true of central nervous system lues. Sydenham's chorea, on the other hand, is a more ideal disease on which to base conclusions as to the effectiveness of this therapeutic agent. The nature of this disease is one of slow progress in which the patient rarely shows marked and spontaneous improvement from one day to another. In my experience I have rarely seen an exception to this statement.

Before any definite statement can be made regarding the effectiveness of forced perivascular drainage in the treatment of poliomyelitis it will be necessary to obtain statistical evidence. Four cases of pre-paralytic polio have been treated in the human, all of which recovered without any paralysis or muscular weakness. This statement from a statistical viewpoint is of course of no value. The clinical observation of the behavior of these patients is of value. The fact that these patients lost their tremor and nervous irritability during the treatment is encouraging. Two patients with bulbar paralysis, existing for three and five days, respectively, showed prompt improvement in their paralysis.

Experimentally produced polio is a very serious disease in the monkey. It is so severe and rapid in its course that it cannot be compared to the human disease. We have been able to treat the monkey with forced perivascular drainage and have definitely modified the course of the disease. (In this work Dr. Chapman has been associated with me and we will subsequently publish a report.)

My present conception regarding the treatment of this disease is as follows. Forced perivascular drainage will modify acute poliomyelitis both in the human and in the Macacus rhesus. The technic which will produce the best results in human polio has not yet been worked out. It is highly desirable that a study of this kind be done by someone who thoroughly understands the subject and is conversant with the technical variations possible.

The pathological findings in Sydenham's chorea have not been constant. Hyperemia, minute embolus, petechial hemorrhage,

and perivascular round-cell infiltration have been reported. The latter has not been a constant finding. This type of chorea has been classified by various authors as an infectious disease, as a symptom of generalized infection, and as a functional disease. Its intimate relation to rheumatic fever is accepted by all. The fact that in all of the fourteen cases which I have treated by forced drainage, round cells were found in the later fractions of the spinal fluid would lead us to believe that a perivascular round-cell infiltration was present in each case, and that the small number of cells obtained in these fractions as compared to the number found in poliomyelitis would argue for a small area involved.

I have summarized my experiences in the treatment of Sydenham's chorea. (See Table VIII.) Fourteen cases have been treated. There has been one failure. In the case that did not improve (case 3), I varied my technic considerably in order to make some pressure studies. (See Table IX.) The spinal needle was attached to a two-way tube, one tube running to a manometer and the other tube being clamped. At intervals the clamp was removed and a small amount of fluid allowed to drain. This type of technic ignored one of the fundamental principles involved, which is mentioned above, that of reducing the pressure of the spinal fluid to atmospheric pressure. Later when I endeavored to give the patient an adequate treatment the mother refused.

I have found that mild cases of hemichorea have been most resistant to treatment. Therefore in the last two cases I changed my solution to 375 per cent NaCl with prompt and complete recovery in two days. Further studies are necessary to determine if this will be constant.

PRESENT TECHNIC AND PROCEDURE

The patient should be prepared three hours previous to treatment by giving food high in protein content and about three glasses of water. In case of dehydration a clysis of normal saline should precede the forced drainage, after which lumbar puncture should be performed with the patient on a Bradford frame. The Queckenstedt sign should then be tested. A specimen of spinal fluid should be gathered for laboratory examination, care being exercised not to remove too much fluid. The stylet is then replaced in the needle and the spinal

needle should be rotated gently in order to enlarge the opening in the dura. The patient is rotated on the Bradford frame with the needle protruding through the window. An intravenous injection of hypotonic solution should be given and in case the patient is delirious or has a severe chorea the internal saphenous vein is the vein of choice for the reason that the foot can be easily mobilized to the frame. In children and babies it is often desirable to tie the needle into the vein. In patients over fifty pounds in weight the injection should be given at the rate of about one liter an hour. When the flow of the intravenous solution has become established the stylet is removed from the lumbar needle and the fluid allowed to drain. If the fluid spurts the stylet should be introduced intermittently until a steady drop has been secured.

The drainage of spinal fluid may now proceed without interruption. If the patient develops frontal headache an ice cap or an injection of codein may be used. If the headache is suboccipital or if it is followed by vomiting the stylet should be inserted for a period of about 15 minutes after which drainage can again proceed. Headache can also be controlled in many cases by increasing the rate of flow of the hypotonic solution.

In case the flow of spinal fluid ceases altogether a slight rotation of the needle upward and the introduction of the stylet into the needle will usually re-establish the flow. Should this occur early in the treatment and should the spinal drip not be established after a period of about 15 minutes, the intravenous should be stopped and a second lumbar puncture done. If it should occur late in the treatment, particularly following a free drainage of spinal fluid, it constitutes no reason for discontinuing the intravenous. Following the completion of the intravenous a very short subsequent drainage should be allowed in selected cases. I am not convinced that this subsequent drainage is of great therapeutic value and it is often advisable to discontinue the treatment at the completion of the intravenous.

Following the treatment it is advisable to give a Murphy drip of normal saline.

I believe that forced perivascular drainage is a safe procedure if understood by the operator and properly carried out. I further believe that the only grave danger is that from cerebellar herniation into the

foramen magnum. The treatment can be carried out in such a way as to prevent the possibility of cerebellar herniation. The recognition of this condition is also possible before any serious accident can occur. In my series I have met this condition twice.

My first encounter with cerebellar herniation occurred after I had been working with this method for two and a half years. This treatment was conducted by one of my associates while I was out of the city. Certain procedures were carried out which were not according to instructions. The patient, a girl of nine, had entered the hospital with acute rheumatic fever. She had developed chorea during convalescence and was treated 10 days after its beginning. A new floor supervisor, unaccustomed to this form of treatment prepared the patient as if for operation. No breakfast or fluids were given; 30 c.c. of spinal fluid was collected for some special laboratory tests. The patient began vomiting at the beginning of the intravenous; 3,000 c.c. of 0.45 per cent NaCl was injected during a period of four hours. The patient vomited six times during this treatment. No occipital or suboccipital headache was complained of. The pulse rate continued around 120 and the respirations at 28 showing very little change during the treatment; in fact, the only untoward event was the vomiting.

After the completion of the intravenous the spinal fluid was allowed to drip for one hour and a half. Five minutes after the completion of the drainage the patient developed severe generalized convulsions with tremors over the whole body. The arms and legs were rigid. There was deep cyanosis. Temperature was 97 degrees; pulse weak, irregular and rapid. The convulsions were controlled by ether inhalations, following which CO₂ and oxygen were given and a hypodermic of caffeine-sodium benzoate (grs. 7½). The patient's condition was improved and a lumbar puncture was immediately done to determine the spinal fluid pressure. This was found to be 4 mm.Hg. Clonus could be easily produced at the ankles and fingers and seemed inexhaustible.

There was a second convulsion four hours later which was less severe and a very slight convulsion a half hour after this. At this time the pulse was 126, respirations 28. During the next twelve hours the patient slept. Her color re-

mained good. She voided several times involuntarily but at no time was there any complaint of pain in the suboccipital region nor was there any retraction of the neck. The next morning she ate her breakfast and seemed none the worse for her experience. The following day her condition was excellent and her choreiform movements had entirely ceased.

The objections to the procedure used in this case are as follows:

1. Food and especially fluids should not have been omitted before instituting treatment.

2. Too much spinal fluid was removed before the intravenous injection was given.

3. The stylet should have been replaced in the needle for a short time on the advent of the vomiting and perhaps a second or third time for a short period in case subsequent vomiting occurred.

4. The hour's drainage following the completion of the intravenous should not have been allowed.

The second case was one of bulbar poliomyelitis with complete paralysis of the throat of five days' duration. There was partial paralysis of the legs, 106 cells in the spinal fluid, 92 per cent lymphocytes, with a pressure of 6 mm. Hg., jugular compression producing increased pressures recorded by the manometer. He was given 2930 c.c. of 0.45 per cent NaCl intravenously. A half hour after the treatment had begun his tongue protruded in the midline and continued to do so. Three hours after the beginning of the treatment his abdominal reflexes which had been absent returned but later were not obtained. His speech was improved. Treatment was further uneventful; no untoward symptoms developed. Following this he was given a Murphy drip of 400 c.c. of normal saline. Having showed considerable clinical improvement, he was given a second treatment 17 hours later. Ability to swallow fluids had not returned. He was given 1,300 c.c. of 0.45 per cent NaCl. There was complaint of severe suboccipital headache but no vomiting. Pulse rate and temperature were not disturbed.

At the completion of the intravenous the patient was given a Murphy drip of normal saline and spinal fluid allowed to drain for one and a half hours. One hour later he was cyanosed and developed a jerky type of respiration. Pulse was irregular, rate 50, poor quality, large, coarse, bubbling râles in his chest. He was placed in a

respirator and expired in ten hours. Autopsy revealed a collar-shaped ridge in the cerebellum from contact with the posterior rim of the foramen magnum. There was marked edema of the brain. It was the pathologist's opinion that herniation was not sufficient to cause death.

Bennett describes the symptoms of cerebellar herniation as follows: "Suboccipital pain with retraction of the head, dysphagia, shallow rapid respirations or slow respirations, cyanosis, pulse slow and irregular, forceful vomiting, bruit heard over the occipital region, blood tinged cisternal fluid. With complete block there is a positive Queckenstedt sign."

With a partial or ball valve type of block he reports a reverse of the Queckenstedt sign, viz.: "On compression of either jugular vein a drop in pressure reading instead of a normal rise, with a slow return to the initial reading, or a slight fall from the initial pressure on combined bilateral pressure with a delayed rise after the release of the jugular compression to a higher reading than the original reading."

In the above case I did not completely realize the dehydration present. A clysis of normal saline ought to have preceded both treatments and the period of drainage following the completion of the hypotonic solution ought not to have been allowed. Bennett advises intravenous injections of hypertonic solution for the treatment of cerebellar herniation. He reported edema of the brain at autopsy following the use of hypotonic solution in cases of suppurative meningitis with cerebellar herniation. He attributes the edema to the use of forced hypotonic solution.

I believe that this explanation of the edema of the brain, in the above case, is caused by the interference with the free drainage of fluid through the subarachnoid channels at the point of compression at the foramen magnum, being influenced, moreover, by the action of the forced hypotonic solution. In six autopsied cases of septic meningitis in my series, treated by the injection of hypotonic solution and by forced drainage, no unusual gross or microscopic hydrosis was found.

I have been concerned with the development of the procedure in forced drainage which will give the optimum result and at the same time insure the safety and comfort of the patient. In early work with this method the treatments which I gave, and which are recorded in the literature,

2. We have been able to perfect a technic such that we can do forced perivascular drainage on *Macacus rhesus* monkeys weighing from five to ten pounds. It is a most gratifying experience to find that we can carry out this procedure with ease and precision.

3. At the beginning of our experiments we inoculated all of our monkeys, both treated and controls, by the intranasal instillation method, using virus obtained from Dr. Simon Flexner (Rockefeller Institute) and Dr. Maurice Brodie (Department of Health Laboratory, New York City). This method was used because it was felt that it simulated the mode of human infection as closely as possible. We found that this dosage overwhelmed the animals and that the disease produced was so vicious and acute that it would be questionable if any method of treatment could be of value. The intracerebral method was then tried—using small doses of virus—very close to the minimal infective dose. In these

groups of animals we have obtained some evidence that forced perivascular drainage may prolong the period between onset of the disease and the onset of marked paralysis and prostration. It is too early to make definite statements, for the sections on these animals have not been completely studied. It can be said, however, that utilizing the knowledge which has been obtained to date, one should be able to give this method of treatment a fairer trial concerning its effect upon the experimental disease in monkeys.

4. The work with animals has taught many things concerning the strength of the salt solution, optimum period of injection and drainage, blood volume, and so on. We feel certain that these factors need further study before the best technic of forced perivascular drainage in the human can be devised.

One should be very cautious in drawing either negative or positive conclusions concerning the value of this treatment at the present.

LABORATORY AIDS IN THE DIAGNOSIS AND MANAGEMENT OF PNEUMONIA

Although the actual diagnosis of pneumonia is made largely on the basis of clinical and x-ray evidence, the laboratory can supply information of great value in treatment, prognosis, and detection of complications. Treatment based on bacteriological findings reduces the mortality from pneumonia caused by pneumococcus type I and, according to some reports, from that caused by types II and VII. (Antipneumococcus serum, type I, is available upon application to the local supply stations or the Division of Laboratories and Research.)

To be effective in pneumonia the serum must be administered early. The earlier the treatment, the greater the reduction in mortality. The determination of the type of pneumococcus inducing the infection is usually made from the sputum, sometimes from a blood culture, and occasionally from the urine.

Laboratory Aids in Diagnosis—I. Sputum for Pneumococcus Typing. Freshly expectorated sputum in a sterile container should be sent to the laboratory at the earliest possible moment. Specimens consisting mainly of saliva are unsatisfactory. The specimen—bloody, blood-stained, or purulent—should be from the deeper respiratory passages. In cases of lobar pneumonia the laboratory will usually be able to report within 24 hours the type of pneumococcus causing the infection. Pertinent data may at times be available within an hour. When the pneumonia is due to some pathogenic microorganism other than the pneumococcus, a cultural examination of fresh sputum will usually reveal the etiological agent. If, as often happens with children, the patient is coughing up no sputum, a specimen for typing may be obtained by holding a swab in the pharynx while the patient coughs.

II. Blood Cultures. A blood culture is

frequently helpful in determining the type of pneumococcus present and thus making possible early administration of serum. It is particularly useful when sputum cannot be obtained. Furthermore, a blood culture can aid in making a prognosis. The chances of recovery from pneumonia without bacteremia are, on the average, about three times greater than when bacteremia is present. Helpful information may also be secured from a blood culture when endocarditis or some other septic complication is suspected.

III. Urine Specimens. Occasionally a precipitation reaction, type specific and of definite prognostic value, may be obtained with urine.

IV. Total White Blood Cell and Differential Counts. A blood count early in the disease will often give information which helps in a diagnostic differentiation between pneumonia and a less severe respiratory infection. When no x-ray of the lung fields is available, it is especially important. A high total white cell count and an increase in the percentage of polymorphonuclear leukocytes are often present before signs of extensive consolidation can be detected by physical examination. A leukocyte count is particularly valuable when the percentage of immature polymorphonuclear leukocytes is recorded. Although the correlation between a low total white cell count and a poor prognosis is not strict, the absence of leukocytosis in a frank lobar pneumonia is an unfavorable prognostic sign. An increasing total white count or a rising percentage of polymorphonuclear leukocytes at the time that defervescence is to be expected, suggests the presence of a complication such as empyema, otitis media, endocarditis, meningitis—(Issued by the New York State Association of Public Health Laboratories, January, 1935, Leaflet No. 5.)

BETWEEN MENTAL HEALTH AND MENTAL DISEASE*

B LIBER, M D, D R P H

Lecturer on Mental Hygiene, Neurological Clinic, New York Polyclinic Medical School and Hospital

In mental ailments transition cases are more evident than in somatic diseases. And because these individuals are frequently looked upon as "normal" people, they seem to me to be of greater importance than slight cases of physical illness.

A headache, a passing attack of indigestion, a "cold," a temporary lumbago, an endurable degree of constipation, a superficial wound, a nosebleed, a small boil, a vague feeling of discomfort are already sicknesses in themselves or symptoms of some disease.

It is not the same, however, with a large number of cases of persons who are mentally ill adjusted to their environment.

But just where does mental disease begin?

The excited manic is mentally ill, but a person who is temporarily angry and violent cannot be called abnormal. At times one is sad and depressed, but that does not put one in the class of persons afflicted with melancholia. Many people are less sociable than the average, more shy and retiring, but that does not mean that they are schizophrenics in a pathological sense. Others are extremely careful and conscientious about their daily duties and about insignificant details, looking more than once, perhaps, to see if they have locked the door, but this mental state should by no means be confused with "*folie du doute*." We may be temporarily mistaken and think that some friend has made fun of us, but this is far removed from the conviction of the unfortunate victim of paranoia. Anyone may believe he is hearing imaginary sounds, but is this to be compared with hallucinatory whispers? And lastly, one can pay too much attention to one's body, exaggerate one's true symptoms and think oneself ill when this is not the case—without being a psychoneurotic—provided one realizes one's error and corrects it.

But let us go a step further and we shall meet maladjusted persons whom the public looks at askance—and with good reason. These are persons who are no longer perfectly balanced but who are not yet really

mentally ill. People who are odd or eccentric in its bad sense, "queer" people, those who are embarrassed and excessively shy or who avoid the company of others or are extremely self-conscious, those who are given to melancholy or chronic irascibility, the true "*malades imaginaires*"—these people are all afflicted with the beginning of the transition from a normal to an abnormal condition. And yet they still function in every day life. Frequently they still perform their work and discharge their duties fairly well, although if placed in unfavorable surroundings or influenced by unfortunate incidents they will be plunged into the vast depths of psychopathic ailments. This is the class of diseases called "intangible" or, by others, functional.

It is well known that between mental health and mental disease there is often no fundamental difference but only a difference of degree. That is why we encounter phases in which cases of mild insanity are difficult to recognize, especially for the general practitioner to whom they first come and who generally dismisses them with the diagnosis "that's nothing," and the advice to "control themselves," "change their behavior," and so on. This happens especially in the immense field of the neuroses and psychoneuroses when the condition is not far enough advanced to be easily detected.

But at the same time a large number of these *transition cases*, provided we have the good fortune to discover them early and the physician has had the necessary experience, are more or less curable or, to be more exact, the patients can be readjusted to their environment. Prevention that may check further progress toward insanity is therefore often possible which is a cogent reason why I regard them as very important.

Psychiatry proper includes these cases also. It is true, but quite often ignores them because they are less interesting than the difficult, serious cases and less spectacular than the fully developed ones.

It is here that we see both the difference and the similarity between psychiatry

* Translated from the French

proper and mental hygiene. The treatment of the transition cases often does not yet constitute a therapy in the true sense of the word. Hospitalization is not necessary and may be harmful. Furthermore, mental hygiene, very nearly the same as general hygiene, while concerning itself with the life of the normal or quasi-normal man and teaching him and his immediate family how to live so as to avoid illness or check it in time, faces and also studies the causes arising from his upbringing and his industrial, social and economic situation which play their part in the etiology of the disease.

One can judge from this how necessary it is to understand these transition cases and what immense good one could do by treating them properly.

Let us illustrate the foregoing by examples taken from two sources—my private practice and practice in a mental hygiene clinic in a large city. There follows a description of 18 typical cases; unnecessary details are omitted.

1. A man of 38, with a wife and children, without being asked, relates his anamnesis from early childhood. His parents were indifferent to him and his father even persecuted him. That gave him the idea that he was good for nothing and in consequence he became very timid and remained so for the rest of his life. Masturbated up to the age of 22. During the war he was in the navy and was ill-treated by his superiors. He went through much suffering and his life was several times in danger. Once the ship to which he was assigned was destroyed by a submarine and he was rescued with great difficulty. He complains of indigestion and believes himself to be very ill. He has peculiar notions about health in general and especially concerning food and has undergone several kinds of treatment by all sorts of non-medical healers. He believes himself "lacking ambition" and "unsociable." He complains of insomnia and constant weariness. He is always thinking of his health, is afraid of illness and especially of cancer. He is of superior intelligence, though an unattractive personality. He is physically weak—13 kilograms under his normal weight. His wife, a pleasant, reasonable woman, when interviewed alone, admits that she does not love her husband, that he is "terribly fussy and tiresome," which means that she hates him but puts up with him, submits to his moods

and has no intention of leaving him. There is a condition of slight *psychoneurosis*, schizophrenic traits, inferiority complex, general asthenia. Of late this has prevented him from working and earning his living, although he puts on a fairly normal appearance before everyone but his wife, to whom he shows his true character. A long course of conventional psychoanalytic treatment by a famous specialist produced no results.

A complete examination and a series of talks in which his condition was explained and the truth revealed to him, restored his self-confidence, corrected his ideas about diet and led him to eat so as to put on weight. Regulation of his physical hygiene permitted him to sleep better. Some directions were given to the wife also.

He went back to work and, although not cured, has for several years been well enough for his needs and those of his family. No relapse. If some unfortunate development in his life should bring a return of his former mental condition, a fresh series of psychotherapeutic treatments would probably have a good effect.

2. This patient is a man 27 years old and complains of pains in the left side of the thorax, being convinced that his heart is affected. Physical examination was negative. Patient does not drink or smoke. He has been "unable to work" for a year and a half. He is even afraid to be alone or to go out unaccompanied; is sure that he could not walk far because his heart "would not allow it." And as in all such cases, if he imagines that he cannot walk, he is unable to walk. He adds, "I can't prove it to you—it's a disease that doesn't show." What chiefly prevents him from going out is his fear of fainting, for he fainted in a train a year and a half before. His fiancée explains that that was the only time that it happened and that he was unusually tired after an extraordinary long and difficult piece of work.

They have been engaged for three years and both say they love each other, although it is my impression that the girl is rather tired of the young man's company. It is more than likely that the purpose of his subconscious belief that he is ill may be to keep his fiancée attached to him, as she feels a sort of obligation to take care of him.

Like the first case, he is also, of course, a psychoneurotic. "You are my last resort," he said to me.

I succeeded in winning his confidence, assured him that his heart was perfectly sound, proved to him that he was able to do much work and even to walk without fainting and showed him the connection between his fears and his relation to his fiancée. Then, after a cautious attempt, he began to work. He followed my advice and now is well again.

Other doctors had told him the same thing, but in a superficial and off hand manner which failed to carry conviction.

3. This patient is a man of 40, with a hypospadias a few millimeters from the normal position of the meatus. He has an inferiority complex. He has never dared to have sexual intercourse. Whenever a young girl tried to become better acquainted with him, he would draw away from her and break off the friendship, through fear of his "anomaly." He is very timid and avoids meeting people, although able to carry on his work and be a useful member of his family (father, mother, brothers, and sisters). He considers himself unfortunate and his behavior and state of mind prove it.

A few explanations cured him—or, rather, corrected his mistaken idea, he married, and the first fruit of this marriage was positive proof for him that he was not abnormal.

4. A sterile woman came for aid primarily because she wished to have children, but it soon became clear that the real problem lay in another direction. She was mentally normal but unstable and ill adjusted to her surroundings. She accused her husband of infidelity in which she was fully justified, although it was easy to see that she would have liked to follow his example. She was quarrelsome and got into all kinds of unpleasant situations, e.g., on the day in which she came the first time to see me she managed to pick a quarrel with her 80-year-old father, who lives with another daughter.

Watching her movements, which is a sort of infallible analysis, I was easily able to see that she had unsatisfied sexual desires. She constantly leaned toward the examiner, touched his hand or his arm and bestowed on him her most engaging smile. Another physician, younger, came into the clinic; as he left, she could not help exclaiming, "What a good-looking man!"

After two or three weeks she began to steady down. She came to realize that she had no one but her husband who would put

up with her whims, provided she forgave his wrong doing, and that it was better to take him as he was. She ceased spying on him. The situation improved. She became more philosophical, so to speak, and less nervous and unhappy. He, too, finding her more friendly, felt more drawn toward her and the problem came nearer to its solution.

5. A girl of 24, recently arrived from England, where, after a year's friendship, and against the advice of her parents, broke with a young man she did not love and started out to make her way in the New World. Although she had no acquaintances over here, she succeeded in finding work in a hair-dressing establishment, where she worked long hours, spending the lonely evenings after work without friends or entertainment. A disagreeable symptom soon appeared and became more and more persistent—a twitching of the head and neck which went on for months. Because she was ashamed of this peculiarity, she quit her work.

There was no diseased condition—as yet. Her physical health was good. Mentally she could discover merely a sadness due to her defect. And her tic was obviously an unconscious but compulsory and necessary act which freed her from the work she detested. A single interview, in the course of which the mechanism that accounted for her twitching was explained to her, was sufficient to help her get rid of it. If it came back at all, as it did infrequently and mildly, it lasted only a short time and soon disappeared completely.

6. A very young man, an excellent university student, of superior intelligence, came in from the country to talk with me about his scientific and philosophical ideas, which he believed to be new and original. He expressed himself in perfect language, expounding his theories with admirable lucidity. There was unquestionably not the slightest element of psychosis. The interview was a pleasure to me as well as to him. When I demonstrated to him that several of his ideas in physics, chemistry, sociology, and philosophy had been known for a long time, he thanked me and asked me to suggest to him sources of information.

Several days after his departure, however, I received a letter from one of his friends from which I quote the important passages as follows:

You have interviewed Mr. X, interested in

proper and mental hygiene. The treatment of the transition cases often does not yet constitute a therapy in the true sense of the word. Hospitalization is not necessary and may be harmful. Furthermore, mental hygiene, very nearly the same as general hygiene, while concerning itself with the life of the normal or quasi-normal man and teaching him and his immediate family how to live so as to avoid illness or check it in time, faces and also studies the causes arising from his upbringing and his industrial, social and economic situation which play their part in the etiology of the disease.

One can judge from this how necessary it is to understand these transition cases and what immense good one could do by treating them properly.

Like the first case, he is also, of course, a psychoneurotic. "You are my last resort," he said to me.

not love him. She really feels indifferent toward both of them.

Her greatest secret is her intimate life in early girlhood—her sexual relations with her brother, a few years her senior. This began when she was 8 years old and continued up till her marriage at the age of 21. From 16 to 21 she used to go with young men without having sexual intercourse with them but during all that time she was copulating with her brother once a week on the average. After her marriage she ceased all relations with him.

A second brother, also older than she but younger than the other, took advantage of her in the same manner now and then but not often. The other members of the family, whom I talked with, did not seem to know anything about these relations between the young girl and her brothers. The parents knew nothing at all about it.

There is a third brother but he is some twenty years older than his sister and left the parental roof early to set up his own home. This brother without knowing it, also played a part in the woman's mental life. When he went off with his sweetheart without going through a civil or religious ceremony, the parents were terribly shocked and pruned—although he has led and leads the most moral life of the entire group, having always been true to his wife and never committed incest. The patient, who was a mere child of eight at the time, made a vow, without anyone asking her to do it, that she would always be good and obedient and never do what her eldest brother was accused of having done. In order to obey these rules of conduct, she imposed punishments on herself, as, e.g., repeating this or that prayer so and so many times. This, it seems, was the beginning of the compulsion from which she still suffers. She was even convinced that the death of her grandmother who had been slowly dying for some time, occurred on the day when she forgot her obligation to say her prayers. Consequently, she felt guilty of her grandmother's death. Her brother's going away with his sweetheart excited the young sister's imagination to such a point that she yielded to the advances of her sixteen-year old brother.

The latter, who has had the largest share in this woman's incestuous life, likewise married but is now divorced. He sees his sister very seldom, as he manages to stay as far away from New York as possible. She claims that he no longer holds any at-

traction for her, although she admits she had once really loved him. Knowing that incest is regarded as a great sin from every point of view, she has always felt guilty, which is doubtless one of the principal causes of her mental abnormality.

The remarkable thing, however, is that this situation—a sense of great guilt, incest, compulsion, enslavement to a detested husband, inability to adapt herself to another man—has lasted so long without deranging the woman's mind more than it has. For, on the whole, she lives on fairly good terms with her immediate family, fulfills her duties without rebelling even if without satisfaction, raises her children as well as the average mother, makes an effort and succeeds in being a good wife. She is even fairly sociable, without being happy, in the midst of the groups she is thrown with in her home and elsewhere. She has a woman friend, a married woman, whom she visits often and who is the only person to whom she confides her secrets. It is not a case of direct homosexuality, but the fact that this patient, so unresponsive toward others, is capable of this close relationship and feels this need of friendship indicates the tendency and direction of this friendship.

It is precisely the fact that this woman who, theoretically, ought to be seriously ill, has instinctively found a way to adjust herself sufficiently and in reality is only a transition case which makes it possible for us to take her case and treat her.

To disentangle the details of this case, only the essential features of which I have related, has been abundantly worth the effort. This work helped me persuade the woman that in spite of her symptoms she was fairly well adjusted to her environment and had little to complain of. It was not possible to persuade her to pay no attention to her compulsion but I did succeed in convincing her that she and her brother were not the only incestuous persons, in fact that incest was fairly widespread.

As is known in such cases the doctor cannot assume the rôle of preacher or moralist, but must do all he can to heal or prevent disease. This, up to a certain point, was successfully accomplished in the case.

9 The patient is a young man, who, just coming out of a maladjusted adolescence, is fairly intelligent, with schizoid tendencies, subject to restless nights, and "shak-

philosophy. Because of his modesty, I believe, the talk was purely impersonal, but I ought to inform you of what he himself did not tell you. He has always been a good student, full of originality. He frequently embarrassed his professors with his difficult questions, and he made a deep impression on the students also. But several of them became jealous and he was reported to the dean of the university as a dangerous atheist and revolutionist. False rumors began to circulate about him—he never took a bath, slept in his clothes and, what was worse, did not drink, was not interested in football, and had never been seen in the society of young women. It was inferred from this that he must be crazy. The first two charges are completely false; if the others are true there is nothing humiliating about them. I am the only person in college who fully understands him.

At first he paid no attention to students' gibes, but of late he has been asking himself whether all these people are entirely mistaken in their idea that he is not right in his mind. That is why I sent him to you. I wished to get your opinion on his mental condition and I wanted you to reassure him if he was all right. But I see that his love of ideas got the best of him and made him forget the real object of his visit to you. He tells me that you did, indeed, say that there must have been some other purpose in his coming than merely that general conversation. And yet he changed the subject and continued the discussion, which he found most enjoyable.

So there we had a young man in good mental health but who, misunderstood by his environment, was being gradually forced to believe that perhaps the crowd was right and he might be mentally unbalanced. Treated by correspondence, he regained his self-confidence sufficiently to continue to hold fast to his convictions. Of course, one of the best means would have been to get him to leave college, or go to some other college, but in his case this advice could not be followed.

7. A boy of 14, splendid physique, and until recently a good scholar, now, though in high school, is falling behind and takes little interest in his studies; is apathetic and answers questions laconically.

His aunt, who came with him told that one day the boy had tried to kill himself by turning on the gas.

He accounts for his state of mind by reason of the treatment he gets at the hands of his grandmother. His mother died from complications owing to heart disease. His brother, younger than he, and the father live with the latter's mother, a very old woman. The other boy seems to be easier to get along with and never worries over anything. But the older one, much more sensitive, hates his grandmother, who is very stern.

"We never have any peace at home," he

says. "Grandma is always yelling at us and scolding us. She finds fault with everything. I can't study my lessons."

"The house is dirty," the aunt adds, "and the food is bad. When I come and try to clean up the house, she won't let me do it. She claims she can do it all herself."

Such a hostile atmosphere is a great misfortune for the young boy.

I sent for the father, a factory hand who did not understand the situation at all, and explained to him what was going on. A change of surroundings produced the desired result and the patient regained his normal condition before it was too late.

8. A woman of 32, mother of several children, suffered since childhood from a compulsion that she must make certain motions a certain number of times, e.g., touch a chair before she sits on it, do something to the dishes before she washes them, turn over the pages backward just so many times while reading a book—once for each member of her family. If she resists this tendency, her work is less well done or not completed. For example, she stops reading the book, washing the dishes.

Intelligent, self-taught, she has read much, including books on psychology—which in this case is not so good. She expresses herself easily.

She has been under treatment in many places—among others, according to her, she underwent for two years the classical psychoanalysis in one of the largest hospitals of New York but without any change.

She is tall, organically sound, and what is usually called pretty. Her married life is not happy, although outwardly she lives peacefully with her husband and children. As she herself says, "It is my fault." She claims she loves her children, but "not fiercely like other mothers."

Her face looks strained and depressed and only now and then shows a faint suggestion of a smile.

Several times she has made up her mind to leave her husband but she does not do it, since she lacks the courage. She would like to get a job as stenographer, her occupation before marriage, which she believes would make her independent economically—and sexually also. Not being married, she could do as she pleased. She would not be concerned as to what might become of her children, knowing that her husband would take care of them. She is having sex relations with another man, but does

not love him. She really feels indifferent toward both of them.

Her greatest secret is her intimate life in early girlhood—her sexual relations with her brother, a few years her senior. This began when she was 8 years old and continued up till her marriage at the age of 21. From 16 to 21 she used to go with young men without having sexual intercourse with them but during all that time she was copulating with her brother once a week on the average. After her marriage she ceased all relations with him.

A second brother, also older than she but younger than the other, took advantage of her in the same manner now and then but not often. The other members of the family, whom I talked with, did not seem to know anything about these relations between the young girl and her brothers. The parents knew nothing at all about it.

There is a third brother but he is some twenty years older than his sister and left the parental roof early to set up his own home. This brother without knowing it, also played a part in the woman's mental life. When he went off with his sweetheart without going through a civil or religious ceremony, the parents were terribly shocked and pained—although he has led and leads the most moral life of the entire group, having always been true to his wife and never committed incest. The patient, who was a mere child of eight at the time, made a vow, without anyone asking her to do it, that she would always be good and obedient and never do what her eldest brother was accused of having done. In order to obey these rules of conduct, she imposed punishments on herself, as, e.g., repeating this or that prayer so and so many times. This, it seems, was the beginning of the compulsion from which she still suffers. She was even convinced that the death of her grandmother, who had been slowly dying for some time, occurred on the day when she forgot her obligation to say her prayers. Consequently, she felt guilty of her grandmother's death. Her brother's going away with his sweetheart excited the young sister's imagination to such a point that she yielded to the advances of her sixteen-year-old brother.

The latter, who has had the largest share in this woman's incestuous life, likewise married but is now divorced. He sees his sister very seldom, as he manages to stay as far away from New York as possible. She claims that he no longer holds any at-

traction for her, although she admits she had once really loved him. Knowing that incest is regarded as a great sin from every point of view, she has always felt guilty, which is doubtless one of the principal causes of her mental abnormality.

The remarkable thing, however, is that this situation—a sense of great guilt, incest, compulsion, enslavement to a detested husband, inability to adapt herself to another man—has lasted so long without deranging the woman's mind more than it has. For, on the whole, she lives on fairly good terms with her immediate family, fulfills her duties without rebelling even if without satisfaction, raises her children as well as the average mother, makes an effort and succeeds in being a good wife. She is even fairly sociable, without being happy, in the midst of the groups she is thrown with in her home and elsewhere. She has a woman friend, a married woman, whom she visits often and who is the only person to whom she confides her secrets. It is not a case of direct homosexuality, but the fact that this patient, so unresponsive toward others, is capable of this close relationship and feels this need of friendship indicates the tendency and direction of this friendship.

It is precisely the fact that this woman who, theoretically, ought to be seriously ill, has instinctively found a way to adjust herself sufficiently and in reality is only a transition case which makes it possible for us to take her case and treat her.

To disentangle the details of this case, only the essential features of which I have related, has been abundantly worth the effort. This work helped me persuade the woman that in spite of her symptoms she was fairly well adjusted to her environment and had little to complain of. It was not possible to persuade her to pay no attention to her compulsion but I did succeed in convincing her that she and her brother were not the only incestuous persons, in fact that incest was fairly widespread.

As is known in such cases the doctor cannot assume the rôle of preacher or moralist, but must do all he can to heal or prevent disease. This, up to a certain point, was successfully accomplished in the case.

9. The patient is a young man, who, just coming out of a maladjusted adolescence, is fairly intelligent, with schizoid tendencies, subject to restless nights, and "shak-

ing in the legs." He complained of sexual impotence, premature ejaculation, nocturnal emissions, pollutions in the daytime when merely thinking of a woman, irritability, and "fear of insanity." He was convinced that all this came from masturbation which he had been indulging in for several years.

In this case, the assurance that his onanism, as he described it, hurt no one and left no consequences, changed him completely. After a few talks, he ceased to be preoccupied with the sexual problems he had created for himself, found a young girl suited to himself, and got a job.

10. A man of 30 who suffered merely from an inferiority complex declared that he was "very nervous and sexually undeveloped." He was found to be anatomically normal. The family situation kept him in a state of mind which it appeared he would never be able to get out of without assistance. At the age of two he was left fatherless; his mother, as in nearly all such cases, shielded him excessively, so that now he was still drawn toward her and unable to find any woman to take her place. His older brother, moved by unconscious jealousy and under the pretext of his responsibility as substitute for the father, raised him as strictly as the mother's vigilance permitted. After I had brought these details to light and had explained the cause of the trouble to the young man (and also to his mother, who still spoils him), he succeeded in changing his way of living and his ideas. He is now married and successfully adjusted to his new environment.

11. This patient is a lad of twenty with schizoid tendencies. He was well "up to a few months ago." He fell in love with a young lady whose mother looked down on him, so that he had to give her up. He tried to drown his sorrow by getting drunk with his friends and neglecting his work. These friends hailing from a section where his mother, a widow, sells newspapers and where the proportion of criminals is above the average, are always armed and frequently resort to fists and revolvers. Later, he thought he might remedy the situation by enlisting in the National Guard, which obliged him to go to the armory one or two days a week. But he could not submit to military discipline and was on the point of deserting and probably bringing down on himself a term of imprisonment when the intervention of a physician induced the military

authorities to consent to his release from obligations. Wanting to leave the city to try his luck out West, he caused a scandal in the family by demanding that his mother give him money which she did not have. Obsessed with ideas of persecution and with the fear of insanity, detesting his mother, who, he said, was always "lecturing him and making a scene," he applied to our clinic. We do not claim to have cured him but, by listening to him and talking with him and his family, we succeeded in bringing back the *status quo ante* and getting him to take a job and give up his dangerous friends.

12 and 13. The two following cases, which at first glance are alike in many respects, seem to illustrate very aptly the difficulty of a differential diagnosis in certain cases of depression and dementia praecox. Two unmarried young men of the same age and very nearly the same line of work both happened to come to the clinic on the same day. Both avoided meeting people, but for different reasons. They feared imaginary dangers and had no desire to live. Neither of them had well-developed hallucinations but were disturbed by vague, incomprehensible noises.

Nevertheless the difference is great. Whereas one was afraid of sickness, the other was obsessed—or believed he was—with the desire and yet the inability to talk with people, especially young women.

The hypochondriac felt his own pulse several times a day. He was in good physical health, ate and slept well, did not remember having any disagreeable dreams, never had an emotional upset, and showed no unfavorable antecedents in his family. He did not go to the theatre or out walking, did not dance, was not interested in women, did not belong to any social group. Notwithstanding the great heat of a torrid summer day, he over-dressed, because he feared catching cold, especially since he was "not strong." He had been told five years ago that he had a heart murmur and he felt that his heart "skips a beat now and then." His expression was very apathetic and he looked at the ground as he talked to one.

The other young man, on the contrary, was rather wide awake and made an effort to understand. When this schizophrenic found himself in the presence of a young woman, he liked to talk with her but did not know what to say. He merely stared at her feet—her shoes, he said—then her

stockings, and did not go any higher than her knees, and he was silent. And yet he admired the fair sex. "Women are lovely and wonderful," he said. He had some young women friends but stayed away from them for fear of doing or saying "some irresponsible thing." He had no sense of inferiority as did the first young man; he felt rather superior to his environment. He has an aunt who is in an insane asylum and his mother, after some "trouble" with her second husband (not the patient's father) spent a few months in a psychopathic hospital. The young man has had an unfortunate childhood. He has never known his father and had never seen anything but quarrels started by his mother until he was put in an orphan house, where he was badly treated, according to his statement. At the age of eight he had an accident—a fracture of the bones of a forearm.

Both men had graduated from public school at 15, the usual age.

Fortunately both were able to throw off their abnormal condition—the former his listlessness, his preoccupation with his health; the latter, the spell which shut him off from the world. Psychotherapy has had its effect.

One may feel some doubt concerning cases of melancholia, but in the first of these cases I was afraid of the consequences and, on the other hand, although in the past dementia praecox cases were given up as incurable, we know now that they can be cured or greatly benefited if taken in hand early enough. That is why I had more hope for the second patient than for the first.

14, 15, and 16. A wife is unhappy and depressed because her husband is out of work and therefore unable to make a living and support his children, the family being dependent on the help of an aunt.

A man had always hoped to become a lawyer and went through law school evening course without difficulty but failed repeatedly to pass the New York bar examinations. He was a clerk in a store and is becoming melancholic. Believes himself inferior to the rank he had hoped to attain but above his present job. Was badly treated in childhood by a cruel father.

A divorced woman who was supporting her children and bringing them up single-handed suddenly lost her entire fortune, \$5,000, in a business venture. Since then

she had been expecting to lose her mind and wanted to commit suicide. She had no hallucinations but dreamed about people coming to take her away by force—a fulfillment of subconscious desires.

These three cases are now cured. In the first instance, where there had as yet been no illness at all, reasoning with the woman and making the situation clear to her was enough. In the second, it was necessary to prove to the patient that he did not really wish to become a lawyer and that he would be better satisfied to remain at his present social level. A few talks with the third produced a remarkable result. The woman is now working as a dressmaker and earning her living.

17 and 18. The abnormal mental state or bad judgment of the parents can have harmful consequences for the children. In these two cases, which were quite as much problems in mental health as in child-rearing, it was the parents and not the children who ought to have been treated or properly brought up.

One mother was convinced that her four-year-old child was nervous, irritated, and ill. The most important symptom she could name was the fact that he moved a great deal during sleep. An examination showed him to be a fine little lad, playful and full of life, as was proper at that age. It was the mother—as one learned after a talk with her, and the father—who was mentally depressed and, believing herself to blame, was sure she had harmed her child and made him mentally unbalanced.

Another mother, who flattered herself that she had read—but ill digested—articles on psychology and modern child-raising, believed her child a grave problem, mentally defective, negative, and disobedient. It is true that the six-year-old boy was a little maladjusted to his environment, but if he had any defects, they were the defects of his good qualities. He had an alert intelligence, above the average (IQ:120), and was gifted with a poetic temperament which his mother was unable to understand. He drew well, talked about his little friends, and expressed himself perfectly.

It is difficult to state what kinds of cases we meet with, but the following data seem to me typical for our dispensary:

Out of 100 cases we have had 20 psychoneurotics and neurotics, 18 cases of melancholia or mental depression, 15 schizophrenics, 5 behavior problems (children), 6 cases of stammering (children),

8 epileptics with mental disturbances (3 of them children), 2 cases of insomnia of mental origin, one of headache of mental origin, 3 convulsive *tics* of mental origin, 7 hypophrenic children, one person sent to us by the court to certify as to his mental condition, 14 without any discernible mental defect.

In other words, 70 cases coming under the head of mental hygiene, with 50 per cent of them showing some improvement or other.

Perhaps the reader will ask what constitutes the psychotherapy for these transition cases. In the first place, as thorough a search as possible for the factors that caused the disturbance. Any source of information is valid for this purpose. One must try to learn about the patient's life from his very birth, also his heredity if possible. Family life, upbringing, influence of the school, factory, shop, church, social and economic background, sex life, poverty, and obstacles of all kinds.

Frequently the cure is accomplished in great part through the opportunity offered the patient to make a full confession, to talk about his case, which he sees much better when it is placed clearly before him. There is also the physical examination, which if it is negative or nearly so, circumscribes the disease and *re-establishes the patient's self-confidence*. *Somatic ailments may be the cause of or an opportunity for mental ailments, which latter may take on the appearance of bodily ills*. One must therefore pay attention to these possibilities.

The very act of talking with the patient and taking an interest in him is in some

cases a great help. But especially, the disclosing of the mental difficulties and untangling of a complicated situation may do a great deal of good. This treatment is not formal psychoanalysis but a *modified and simplified analysis*.

Psychiatrists who are trying to make use of suggestion—that is to say, to counteract autosuggestion—are sometimes adversely criticized, but I believe they should be free to use *all* psychic means available and apply them according to the particular case. This is why it is *impossible to give hard and fast rules for these conversations*.

Of course, medication is also frequently employed in certain instances temporarily, as in insomnia. Nor are the diet, hydrotherapy, and other physiotherapeutic means to be overlooked.

I address myself both to the general practitioner and to the specialist.

I wish to emphasize the great importance of these cases, where much harm may be done or great help may be afforded. They should never be misunderstood or neglected by the physician at large.

The first clinic, as far as I know, where this work has been in practice is that of Professor Toulouse of Paris, where I have followed it for some time. In this country the Outpatient Department of the New York State Psychiatric Institute should be mentioned in this regard, where I have recently worked and studied.

I would make a plea to attract the attention of the able specialist to use his great skill and experience in studying and treating these humble transition cases more than they have been in the past.

611 WEST 158TH STREET

DIPHTHERIA DISAPPEARING

Diphtheria is becoming one of the rarest of diseases, according to the New York State Department of Health, which makes public figures showing that in 1934 only 442 cases were reported to the department. In 1914 there were 5,408 reported cases outside of New York City, and in 1924 there were 5,883. Thus the number has been reduced in the past ten years by over 92 per cent.

The small number of cases, the department reports, is attributable mainly to immunization of young children against the disease, although, so far as is known, immunization does not prevent the diphtheria carrier state.

The department officials, as quoted in the *New York Times*, believe that "no sizable community is without diphtheria carriers, and

in the light of present knowledge there seems little or no possibility of controlling every source of diphtheria infection." In spite of the rarity of clinical cases, the department states that "vigilance cannot be relaxed."

"The protection of every child, particularly in densely populated communities, by means of artificial immunization during the first year of life is still the goal to be attained," the statement says.

Two cities, Binghamton and Niagara Falls, and each having more than 50,000 population, had no cases in 1934, "an event which, according to morbidity records extending back to 1908, has never occurred before in New York State." The percentage of children immunized was 40 and 43 per cent.

THE IMPORTANCE OF MEDICAL SUPERVISION DURING EARLY INFANCY ON THE INFANT DEATH RATE

HARRY BAKWIN, M.D., AND RUTH MORRIS BAKWIN, M.D.

From the Children's Medical Service of Bellevue Hospital and the Department of Pediatrics, New York University, and the Fifth Avenue Hospital, New York City

The purpose of these observations was to determine the effect of medical supervision on the growth and health of infants from a poverty environment.

Three groups of infants were studied.¹ One group consisted of infants admitted to Bellevue Hospital as healthy boarders or because of mild upper respiratory infections. The homes from which they were derived were, for the most part, very poor, the usual family income in 1929

partial or complete relief aid. The group is predominantly "North European" (Irish-American). These infants received no regular medical supervision before admission to the hospital. There were 534 infants measured 798 times.

The second group consisted of infants born in Bellevue Hospital and residing in its vicinity. They are, economically and racially, identical with the group just described, differing only in that they were

Chart 1. Comparison of the growth in weight of Bellevue Hospital supervised infants (continuous lines), unsupervised infants (dotted lines) and Fifth Avenue Hospital infants (averages represented by crosses)

being between \$15 and \$22 per week. Employment in this group has always been irregular, total unemployment for periods of weeks being common. In September, 1932, when this study was nearing completion most of the families were receiving

supervised throughout infancy in a special clinic. They were first seen at about 3 weeks of age and were observed thereafter at monthly and often at shorter intervals, particularly during the early weeks of life. Advice was given regarding diet, isolation

from infection, and general care. Breast feeding was encouraged. For artificial feeding, whole or evaporated milk, with added cane sugar, was used. Egg yolk was introduced in the third month of life, cereal and vegetable in the fourth month.

mately the same rate, the weight and height of the Bellevue Hospital group being only slightly below that of the Fifth Avenue Hospital group but still somewhat higher than the "normal" values given in most textbooks. There is a delay in the

Chart 2. Comparison of the growth in height of Bellevue Hospital supervised infants (continuous lines), unsupervised infants (dotted lines) and Fifth Avenue Hospital infants (averages represented by crosses).

Orange juice and codliver oil were given routinely after the first month. No other antirachitic aside from sunlight was used. The average caloric intake was between 50 and 55 calories per pound. About 12 minutes per patient was allotted by the physician at each visit. There were 352 infants in this group measured 1,050 times.

The third group consisted of infants born at the Fifth Avenue Hospital and supervised there in a special clinic. The economic environment of this group was considerably better than that of the other groups, family incomes in 1929 averaging between \$30 and \$35 per week and employment being much steadier. The medical supervision was identical with that at Bellevue Hospital. There were 514 infants in this group measured 1,405 times.

The growth in weight and height of the 3 groups is compared in Charts I and II. The 2 supervised groups grow at approxi-

unsupervised group, however, which becomes apparent in the second 4 weeks of life. It is more marked during the 8 to 15 week period but thereafter growth in the 3 groups continues at the same rate, with the unsupervised group at a lower level. This is shown in Chart III which illustrates percentage growth rates for the 3 groups, calculated by the method of Brody² by 12-week periods. Changes in the growth of other external and internal body dimensions are published elsewhere.^{3, 4, 5}

In Chart IV the growth in total body length and weight of infants dying of various causes (267 cases) and surviving infants (Bellevue Hospital unsupervised) is compared. The infants who died were, on the average, shorter and weighed less than those who survived. Though weight may have been influenced by severe illness, it is hardly likely that total body length

could have been so influenced since death in infants is only rarely dependent on long standing illness.

One of the commonest causes of infant death in the Bellevue Hospital population is acute intestinal intoxication. In Chart

V, the total body length of infants with this condition (220 cases) is compared with that of the Bellevue Hospital unsupervised group. Infants with acute intestinal intoxication are, on the average, shorter than the control group. Weight comparisons in

Chart 3. The percentage growth rates for various body dimensions by 12 week periods during the first 48 weeks of life. Solid columns represent the Fifth Avenue Hospital group, blank columns the Bellevue Hospital supervised group, and cross hatched columns the Bellevue Hospital unsupervised group.

Chart 4. Comparison of the total body length and weight of healthy infants (continuous lines) and infants who died (dotted lines).

this disease are useless since the onset is accompanied by a marked weight loss. In Chart VI, however, the weights of 67 infants, measured before they developed acute intestinal intoxication are shown. It can readily be seen that it is the under-weight as well as the under-height infant who develops this condition.

It is evident from these observations that the crucial period for the prevention of severe illness and death in infancy is the early weeks of life. This period should be stressed, if necessary for reasons of economy, at the expense of supervision during the later months of the first year. With modern dietary régimes little change is necessary after 6 or 8 months and infants

properly supervised during the first half year can be seen safely at 2 instead of 1 monthly intervals during the second half year.

Summary

1. The growth of infants from a poverty environment may be raised to normal levels solely through the agency of medical supervision.

2. The delay in growth of unsupervised infants occurs almost entirely within the first 12 weeks of life, growth thereafter continuing at the same rate but at a lower level than in supervised infants.

3. Undergrown infants become seriously ill and die in higher proportion than infants who grow normally. 132 EAST 71ST STREET

Chart 5. Comparison of the total body length of healthy infants (continuous lines) and infants with acute intestinal intoxication (dotted lines).

Chart 6. Comparison of the body weight of infants who developed acute intestinal intoxication at a later date and healthy infants. Circles represent individual cases.

COMMUNITY CONTROL OF PROFESSIONAL BLOOD DONORS

E. H. L. CORWIN, PH.D.

Secretary and Treasurer of the Blood Transfusion Betterment Association of New York

Need of Community Control

In response to the increasing use of blood transfusions as an important therapeutic device came the need of safeguards in the use of it. None of the safeguards is more important than carefully made compatibility tests and the freedom of the donors from diseases which can be transmitted with the blood, such, for example, as syphilis or malaria. It is, of course, possible for each hospital to cultivate its own group of "donors," to examine them periodically, and to make with them suitable arrangements. No individual arrangement can, however, assure a given institution of a supply of donors of the rarer types, nor can a single institution regularize the employment of donors. These things are possible only when a number of institutions agree to employ donors through one avenue. It is with this in view that the Blood Transfusion Betterment Association was organized in New York.

Origin of the Blood Transfusion Betterment Association

The Blood Transfusion Betterment Association is an expansion of the work of the Co-operative Blood Donors Bureau originally established in New York Hospital by Dr. Arthur F. Coca in response to a demand by hospitals and physicians for donors who had been reliably examined and approved by means of tests. Up to that time only commercial agencies had been in existence and were outside of the pale of any control. A large proportion of their donors were too often recruited from the less responsible elements of the community, and were used without much consideration for any one concerned. In 1930, largely through the efforts of the Blood Transfusion Betterment Association and of the Committee on Public Health Relations of The New York Academy of Medicine, additions to the Sanitary Code were made, designed to correct this evil.

Organization

The Blood Transfusion Betterment Association was incorporated as a non-profit making organization. All of the hospitals

and doctors in the city can use the services and those paying annual dues of \$10 are eligible for membership in the Association.

The Association functions under the direction of a Board of Trustees which appoints annually a Board of Medical Control of eleven members to direct its medical activities. Five of the membership of this Board are ex-officio representatives of the New York Academy of Medicine, the New York Pathological Society, the Department of Health, the Department of Hospitals, and the five County Medical Societies of Greater New York. An executive Medical Director is appointed to be in immediate charge of the work.

Most of the members of the Medical Board are experts in either hematology or the practical aspects of blood transfusion. One of them is the leading authority on blood grouping, Karl Landsteiner, M.D., of the Rockefeller Institute, and Nobel Prize winner in medicine in 1930, whose work on blood grouping has played such an important part in the use of transfusion as a therapeutic practice. The invaluable advice and assistance of Dr. Landsteiner are always at the disposal of the Association. The laboratory and clinics are under the experienced guidance of Dr. Coca. Through the very able business direction of Mr. Henry C. Wright, the Manager of the Association, the financial status of the Bureau has improved to such an extent that during the past year it has been possible to pay the Medical Director a moderate salary for continuous service, and to undertake research work.

Aims and Purposes

From the beginning a comprehensive program was devised for the Blood Transfusion Betterment Association, with activities in many directions. In addition to supplying donors for the use of physicians and hospitals it was planned that the Association should sponsor important researches in the technic of transfusion and the indications for it, as well as postgraduate training in all aspects of the work.

As stated in the articles of incorporation of the Association its aims and purposes are as follows:

this disease are useless since the onset is accompanied by a marked weight loss. In Chart VI, however, the weights of 67 infants, measured before they developed acute intestinal intoxication are shown. It can readily be seen that it is the under-weight as well as the under-height infant who develops this condition.

It is evident from these observations that the crucial period for the prevention of severe illness and death in infancy is the early weeks of life. This period should be stressed, if necessary for reasons of economy, at the expense of supervision during the later months of the first year. With modern dietary régimes little change is necessary after 6 or 8 months and infants

properly supervised during the first half year can be seen safely at 2 instead of 1 monthly intervals during the second half year.

Summary

1. The growth of infants from a poverty environment may be raised to normal levels solely through the agency of medical supervision.

2. The delay in growth of unsupervised infants occurs almost entirely within the first 12 weeks of life, growth thereafter continuing at the same rate but at a lower level than in supervised infants.

3. Undergrown infants become seriously ill and die in higher proportion than infants who grow normally. 132 EAST 71ST STREET

Chart 5. Comparison of the total body length of healthy infants (continuous lines) and infants with acute intestinal intoxication (dotted lines).

Chart 6. Comparison of the body weight of infants who developed acute intestinal intoxication at a later date and healthy infants. Circles represent individual cases.

Academy of Medicine were instrumental in incorporating in the Sanitary Code Donors must carry their Department of Health passbook when responding to calls. If for any reason the applicant is rejected by the Department of Health he is not accepted for registration by the Bureau. Among the data recorded in this passbook is certain essential information for identification purposes, including the donor's photograph, his blood type, and the amount of blood taken at each transfusion.

Periodic Re-examination

A Wassermann test of every donor registered with the Association is made regularly at the Department of Health Laboratory every six months, and the date of the last examination is indicated in the donor's passbook as a certification that his test was negative at that time. The Association's laboratory further controls the donor by a Kahn test every six months, alternating with the Department of Health Wassermann examination. In effect, the donor thus receives a serum test for syphilitic infection every three months.

After a donor has submitted to a transfusion he must remain off the active list for one week for each 100 cc of blood given. Before he may be used again he is given a complete physical examination at the clinics of the Association maintained for this purpose. At that time a fresh hemoglobin reading is also made. The standard set by Dare is used and no donor is utilized whose hemoglobin is below the minimum of 85 per cent.

In the donor's Department of Health registration book is entered the record of the date of each examination, the percentage hemoglobin and other results of the examination under the signature of the examining physician.

There is also recorded in this passbook the date of each transfusion, where it was made, the amount of blood taken, the result of the routine examination of the donor, and the signature of the physician performing the transfusion.

Donors are supplied with a pamphlet of instructions to insure intelligent co-operation on their part in the mechanics of operating the service, and giving them simple information as to their habits and general health.

Every effort is made to safeguard not only the patient but also the donor—the latter particularly against too frequent

donation of blood, infection—or unnecessary cutting down on the veins.

How the Bureau Functions

As indicated in the foregoing description of the examination procedure of applicants for registration, prospective donors are first examined and classified as to blood type at the clinic of the Association. A record of the results of the examination and typing of each candidate is kept on file for ready reference.

A card index of the donors available and on the active list at any given time is kept within hand reach of the attendant on duty. The service is on a 24-hour basis, 365 days of the year. Almost nightly from one to several emergency calls are received at the office.

When a request for a donor is received at the office entries are made of the name of the patient, the name of the hospital, or of the private physician as the case may be, the type of donor needed, and the urgency of the call. Subsequently the hospital is given the name of the donor assigned and the approximate time of his arrival. Donors are sent by taxicab whenever the time element is especially important, and in all instances an effort is made to avoid unnecessary delay in transit by assigning a suitable donor from as near the vicinity of the hospital as possible.

On the receipt of a call the office attendant consults the card index and gets in touch by telephone with a donor who meets the requirements as to blood type and any other necessary qualifications.

Upon receiving the telephone message the donor proceeds at once to the hospital where he reports his presence to the proper office where his credentials are examined and the type checked to make certain that he meets the requirements.

Established Rates of Pay

Following the transfusion, the donor is expected to rest for one hour. After this he proceeds to the cashier's office of the hospital where he is paid for his services at the rate of \$7 per 100 cc of blood. The amount of blood withdrawn is entered in his passbook. This constitutes a voucher to the cashier as well as a guide to the Association, of the next availability of the particular donor. No donor is used again until as many weeks have elapsed since his last transfusion as hundreds of cubic centimeters of blood were withdrawn. In other

words, a donor from whom 500 c.c. was taken is not available until five weeks have elapsed since his last transfusion.

Conclusion

The recognition which the Blood Transfusion Betterment Association has received in New York, and the organization of services along similar lines in Paris, Brussels, London, Berlin, will, no doubt,

stimulate the adoption of similar community safety devices in all other large population centers. Each city of considerable size, together with its suburbs or satellite towns, can establish an organization similar in its essential service features to the Blood Transfusion Betterment Association of New York without great difficulty or cost.

2 EAST 103D STREET

SOME PLAIN TALK

A few "jolts to the jaw," in the language of the day, were given the advocates of health insurance in the presidential address of Dr. Michael Canick to the East New York Medical Society. He said in part:

"At no time in human history have the people gotten a better dollar's value in medicine than at the present, what with our improved diagnostic and therapeutic methods. There never was a time nor was there ever a trade or a profession where people obtained valuable service without pay, as in our profession at the present moment. Not only the indigent and collar classes but the chisler—in the bargain—is availing himself of this immense free service. They lie, therefore, who claim that certain classes of people obtain no medical service—especially in the city.

"Equally false is the statement, accompanied usually by crocodile tears on the part of the social workers, that the doctors are starving. I fervently declare that to be even a greater lie. The old timers will bear me out, when I say that 20 years ago it was considered successful to make rental the first year and cover your immediate needs by the end of the third year. The immediate needs were very modest; a two-room office, without elaborate equipment, without automobiles, and other comforts. The doctor worked ten times as hard and obtained less than one-quarter than at present, both relatively and absolutely. The cost of living was then half of what it is now but the income was less than one-quarter. The only income the doctor ever derived then, was from office visits at 50 cents and 25 cents per, outside calls at \$1 per, and confinement cases at from \$5 to \$12 per, often necessitating nights and nights of sleepless vigilance.

"Struggle and hardship! I say to the younger men—you don't know what struggle meant. If only we were to eliminate the chiseler class from our free clinic and hospital service—a thing easy of accomplishment; if we only sublimate our grumbling into concerted action—there will be more than enough to go around, despite the dispro-

portionate increase of doctors to the population.

"Discounting therefore, all the ballyhoo, and the exaggerated emphasis upon our existing faults, the problems of the medical profession can be summarized briefly as consisting of the question of how to make a decent and respectable living for ourselves, and at the same time give adequate medical treatment for poor and rich alike—a problem to be solved by our own peers and not by lay people lording over us. In other words my slogan is: Medical liberty or Medical death. Socialized medicine far from solving our problems will merely increase taxation; will poison medical science with politics; will deprive patients of the most valuable part in the art of medicine—personal confidence and sympathy between doctor and patient; will impede scientific progress and initiative; and will be discriminatory to the medical group by forcing it to live an isolated existence on a socialistic island in the sea of capitalistic society."

A rather strange feature of the prevalence of measles in New York City is that it shows a marked increase every second year. The city department of health reports that in the control of measles the injection of parent's whole blood into children who are known to have been exposed to infection has proven of value. The technic is simple. Physicians may obtain a pamphlet describing the method in detail by writing to Dr. Charles Bolduan, Department of Health, 139 Centre Street, New York City, and by asking for "Measles Reprint."

Some good work has been done by the Westchester County Society during the past year in giving the State Board of Medical Examiners considerable information regarding the illegal use of the term "Dr." by optometrists, chiropractors, and the like without the proper qualifications as required by law and also by several unlicensed practitioners in the county. The Board of Examiners has welcomed these complaints and has acted promptly to have such abuses stopped.

Facts vs. Calumny

Opponents of the Medical Abuses Bill have attempted to hide the real issues at stake behind a smoke screen of calumny against organized medicine and the medical prosecuting agencies of the state. If any refutation of these unfounded charges is necessary, it is furnished by the official records of the State Education Department and the Medical Grievance Committee.

Having deprived the profession of any voice in the administration of workmen's compensation, those opposed to the free choice of physician are now attempting to shift the blame for the consequences from their own shoulders by accusing the state and county medical societies of delinquency in failing to weed out incompetent and corrupt practitioners. It is incredible that the calumniators of organized medicine do not know that its disciplinary powers extend only to violations of the ethical canons of practice. Even the Grievance Committee's jurisdiction is limited to strictly defined circumstances.

In spite of this sharp circumscription of authority, considerable progress has been made in the eradication of charlatanism within and without the profession. This is attributable solely to the splendid co-operation existing between organized medicine, the State Department of Education, the Grievance Committee, and the Assistant Attorney General in charge of medical practice.

Since the amended Medical Practice Act went into effect in 1926, more than 3,395 complaints have been investigated, of which approximately two-thirds showed cause for action. Close to 1,500 violations were stopped without court procedure. Of the 562 cases in which prosecution was instituted, the remarkable proportion of 84 per cent resulted in convictions.

In the six years from September, 1928, to July, 1934, the Medical Grievance Committee disposed of 355 complaints against physicians, embracing a wide variety of offences. As a result of its investigations, eleven licenses were revoked, six suspended and formal censure administered in eight cases. The disciplinary activities of the Grievance Committee have had a twofold aim—not only to curb irresponsible practitioners but to protect reputable physicians against unwarranted charges of incompetence and malpractice.

No small part of the excellent results cited is due to the vigorous policy pursued by the State Department of Education. It is not mere chance that no chiropractic bill has been introduced in the State Legislature in the past two years or that henceforth the requirements for admission to osteopathic schools will be the same as for medical college.

The splendid work of Dr. Harold Rypins and Deputy Attorney General Ullman negates loose talk of uncurbed

malfesance in medical practice, just as the accomplishments of organized medicine controvert the ridiculous charges leveled against it. In no other field of human activity has as severe a discipline been self-imposed for the elevation of professional standards and the furtherance of the public good.

An Undesirable Anomaly

The more imminent danger of compulsory health insurance has served to divert attention and criticism from the aims of the Medical League for Socialized Medicine. Going further than most of the lay reformers who desire to modify the economic pattern of healing, this little group of physicians is prepared to abandon the entire framework of the past for the dubious shelter of governmental employment.

It is difficult to understand how physicians can be willing to throw overboard the traditional personal relationship between their patients and themselves unless they view healing as no more than a mechanical trick of fitting designated remedies to specified ills. Unfortunately this narrow concept of practice dominates the attitude of most of those endeavoring to subordinate the doctor to bureaucratic control. It so far colors the theories of the Medical League for Socialized Medicine that this body of doctors wishes to destroy the free choice of physician, giving district hospitals the right to designate medical attendants for patients within their jurisdiction. A strange form of socialism this, which takes from the mass of the people a fundamental right which they have always jealously cherished.

The platform of the Medical League for Socialized Medicine does not derive strength from comparisons with the postal service or the schools. In the handling of the mails, it is the system rather than the individual which counts. While this is not true in teaching, mass methods are nevertheless more practicable in education than in healing. The teacher deals with classes, but every medical act is individual and gains in effectiveness as it is adapted to the requirements of the particular

patient. It is this modification of general principles to the individual organism which makes for quality in practice, and it is precisely this element which is lost under compulsory health insurance or the impersonal system advocated by the Medical League for Socialized Medicine.

In return for the sacrifice of independence and opportunity which they are prepared to make, the medical advocates of state medicine envisage secure jobs and a steady income for all practitioners. This halcyon dream is shattered by the experience of the very teachers and mail-men whom the officers of the League hold up as an example. When the political bosses of Chicago emptied the treasury, the teachers of that city went unpaid for months. The story of the depression is replete with wholesale dismissals of government employees and extensive pay cuts. Teachers have been on waiting lists for years without seeing job or salary.

Fortunately the misguided members of the Medical League for Socialized Medicine are not likely to have an opportunity to suffer the consequences of their unsound scheme. In a state which must look to taxation for all moneys, it is not feasible for the government to take over the responsibility of medical care for the entire population. Capitalist nations do not furnish suitable soil for socialized medicine.

Fatalities from Appendicitis

No less an authority than Dr. Charles Gordon Heyd stated recently that "within very definite limitations, there should be no deaths from appendicitis." Nevertheless, the *American Journal of Surgery* presents the startling announcement that in this country, a death occurs from appendicitis every thirty-three minutes. In his address before the New York Academy of Medicine, Dr. Shepard Krech¹ stated that an average of eleven hundred persons died annually of appendicitis in New York City during the last six years.

¹ Krech, Shepard: The Problem of Acute Appendicitis in New York City, *NEW YORK STATE JOURNAL OF MEDICINE*, Vol. 35, No. 6, March 15, 1935.

That these figures are disturbing and should lead to correctional measures is obvious. Cases should not come to surgery with proof of neglect and delay. The tragical error of administering cathartics must be avoided. Better and surer early diagnosis, and the realization on the patient's part of the gravity of appendicitis, must be comprehended. Procrastination and surgical postponement have no place in therapy. A better understanding of both preoperative and postoperative care will help better the therapeutic results of surgery.

The root of the grave crisis in appendicitis mortality may lie in the fact, as the *American Journal of Surgery* hints, that "familiarity breeds contempt." Our belief that appendicitis had been conquered made us over-confident. The realization of our mistake is the first step toward further progress.

The Limitation of the Bacteriophage

We were startled some years ago by the news that "a bacteriophage" had been discovered. Twort and d'Hérelle held out the hope that by the administration of a bacteriophage, the body would quickly rid itself of pathogenic organisms, and by this means even such scourges as plague, cholera, and typhoid could be conquered.

But what seemed the dawn of a new day soon turned out to be a very cloudy sunrise. A test-tube is one thing, and a sick human is another. What succeeded *in vitro* did not work so well, or completely failed, *in vivo*.

For six years commercial bacteriophage preparations have been on the market. None has yet been accepted for inclusion in New and Non-official Remedies by the Council on Pharmacy and Chemistry of the A. M. A. In spite of vast literature, there is confusion, and the Council authorized the publication of a report made by Drs. Monroe D. Eaton and Stanhope Bayne-Jones, of Yale University School of Medicine, who having made an exhaustive investigation of the entire matter, made a report on what they find to be true, and what they term false, what is

valuable, and what is worthless in the use of the bacteriophage. This report¹ should be studied in detail by those interested who wish to be fully informed.

These investigators found that the human blood or serum apparently inhibited the activity of the bacteriophage, and this explains why it acts *in vitro* better than *in vivo*. But, if such is the case, why does it work in the human body at all? The investigators report that "the favorable results may have been due to the specific immunizing action of bacterial proteins in the material used, and to non-specific effects of the broth filtrates." As for the "bacteria eater" itself, "there is no evidence that lysis or killing of bacteria by bacteriophage occurs *in vivo*, except possibly in the bladder, and in walled-off spaces where little exudate is present, and where irrigation with large amounts of bacteriophage can be used."

We Destroy Ourselves

By direct advertising to the laity, certain drug manufacturers have made marked inroads upon both medical and pharmaceutical practice. Physicians should not order preparations so advertised. The medical profession has helped to build up the common use of controlled-name proprietaries by sheer apathy in the matter of prescription writing. It can destroy the evil it has helped to create by vigorous eschewal of products that conflict with its own and the public welfare.

Prescription writing is rapidly becoming a lost art, as doctors rely increasingly on widely advertised products.

Physicians are in a strong position to discourage the evils that have grown out of the widespread employment of controlled-name preparations. The U. S. Pharmacopoeia, the National Formulary, and New and Non-official Remedies, contain the equivalent of almost every proprietary in current use. Wherever possible, the profession should order the products listed in these authoritative guides.

The proprietary substance almost in-

¹ *Journal A. M. A.*, Dec. 8, 15 and 22, 1934.

variably is more expensive. In the patient's interest, write your own prescription.

The Narcotic Evil

In the recent Federal activity against criminals, the round-up brought in, among others, illegal drug vendors of habit-forming drugs. There is an aspect of the question of controlling addiction to habit-forming drugs to which preventive measures could well be applied.

Competent authorities contend that the international control of the manufacture of these habit-forming drugs would be the first real step toward the suppression of the illicit traffic. Knowledge of legitimate medicinal requirements in each country, production strictly controlled and manu-

facture limited to that requirement, would so curtail the supply that there would be little of these drugs available for illegal uses. The Health Committee of the Assembly of the League of Nations has the matter under consideration now.

Adscititious to the question, a more healthy viewpoint is current among physicians. Informed opinion today does not hold the physician responsible for the prevalence of addiction, nor does each arrest of an addict or a vendor cause a cry to be raised demanding more stringent supervision and control of the physician's use of habit-forming drugs in the course of medical practice. The truth of how small a rôle he plays in the causation of addiction seems to have become generally comprehended.

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked "private." All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.]

New York City
March 13, 1935

To the Editor:

In the March 1 issue of the JOURNAL you published certain statements taken from my report on the German Sick and Health Insurance. In doing so, you created the impression that it is my opinion that the German Sick and Health Insurance has been completely insufficient and unsatisfactory for both doctor and patient. This is, of course, not the case.

When, some months ago, the President of the New York Academy of Medicine suggested that I write on my lengthy experiences in and with the German Sick and Health Insurance, I felt highly gratified. I did so, motivated mainly by the desire to help other

countries avoid the mistakes made in Germany. I bared all possible mistakes, errors, and deficiencies of the German system, but made it clear nevertheless that the German Sick and Health Insurance possessed numerous admirable features.

I am firmly convinced that a well organized Sick and Health Insurance System is of greatest possible advantage to both doctors and patients. The value of this system for the people has been fully recognized in Germany, especially in the smaller cities.

Thanking you in advance for publishing my views in the next issue of your paper, I remain

Very sincerely yours,

M. M. ZACHART, M.D.

SECOND ANNUAL NOBEL DINNER

World Peaceways, a "non-profit organization for public information on peace and international affairs," has arranged that its second annual Nobel Dinner will be held on Tuesday evening, April 9, 1935, at the Waldorf-Astoria Hotel in New York City.

At this dinner Dr. Arthur J. Bedell of Albany will be one of the guests of honor representing as President the Medical Society of the State of New York.

Invitation is extended by World Peaceways to all members of the Medical Society of the State of New York to make reservations at this subscription dinner to the Nobel Prize winners.

Inquiries for reservations should be addressed to George J. Ryan, Chairman of Dinner Committee, c/o World Peaceways, which has offices located at 103 Park Avenue, New York City.

Society Activities

Committee on Scientific Work

Dr. Krieger, in charge of the Scientific Exhibit at the Annual Meeting in Albany, May 13 to 15, announces that all possible space for this exhibit at the Hotel Ten Eyck has been assigned and that no further applications should be made as they can only be accepted provisionally.

WILLIAM A. GROAT, M.D., Chairman

Committee on Legislation

SPECIAL BULLETIN, MARCH 19, 1935

The Medical Abuses Bill passed the Assembly the afternoon of March 19 and will go to the Governor for his signature.

Let us transfer our wholehearted support to our Hospital Lien Bill, Senate Int. 1266, Print 1895, now in Rules Committee in the Assembly. Wire immediately to your Assemblymen urging their support of this measure.

HARRY ARANOW
B. B. BERKOWITZ
B. WALLACE HAMILTON
JAMES F. ROONEY
LEO F. SIMPSON
Committee on Legislation

Committee on Public Health and Medical Education

The Committee has been devoting considerable time to the study of pneumonia. In co-operation with the New York State Department of Health and the Metropolitan Life Insurance Company plans have been developed to combat more effectively this common and dreaded disease. The agencies concerned in this endeavor realize that little can be accomplished without the co-operation of the public. Publicity and educational methods to be employed should result in more serious efforts on the part of the public to assist the medical profession and health officials to lessen the incidence of pneumonia and, by early medical and nursing care, to lower the death rate.

The scientific knowledge regarding the causes and specific treatment of certain types

of pneumonia has been laboriously and expensively ascertained. Greater effort should be made to disseminate this knowledge. Some of the most important information regarding pneumonia which should be impressed upon the public is that:

(1) Pneumonia is one of the chief causes of death.

(2) Pneumonia is always—although there are yearly fluctuations in the incidence—one of the group of diseases which takes the greatest toll of life.

(3) Pneumonia is caused by certain kinds of bacteria.

(4) These bacteria are transmitted from one person to another in the discharges of the throat and nose.

(5) Pneumonia works fast. The incubation period is short. The onset is often abrupt. The course of the disease is rapid.

(6) A person with a severe cold, which is often accompanied by a chill, chilly sensations and pain in the chest, should go to bed, remain quiet, and send for his physician.

(7) Early diagnosis is essential if much is to be accomplished by specific treatment.

(8) Competent nursing care is very important.

(9) Laboratory service is necessary to determine the type of bacterium causing the disease.

(10) A sputum specimen and a blood culture should be obtained as soon as possible.

(11) In certain types of pneumonia serum treatment, if used early, yields good results.

(12) Self diagnosis and the use of home remedies too often delay calling the physician early.

Announcements will be made by the Committee concerning the statewide measures to be employed by the organizations interested in this effort to reduce sickness and deaths from pneumonia. Suggestions and inquiries regarding educational and publicity methods, laboratory facilities, or other features of the program will receive careful consideration if addressed to the Committee on Public Health and Medical Education. Thomas P. Farmer, M.D., Chairman, 608 East Genesee Street, Syracuse.

"BRANDING THE MAVERICKS"

The doctors are keeping a keen eye on the legislators to see how they vote on measures touching the profession. In picturesque phraseology the *Journal of the Indiana State Medical Association* gives this advice:

"Let us inquiringly search out the legislative mesquite and the administrative underbrush and unmistakably brand with blackball

votes those mavericks whom we have reason to suspect of long-haired theories and pop-eyed reforms as regards goose-stepping the medical profession. Politely, yet firmly insistent, let us present the wool-gatherers with one-way tickets to their farms and forges and ribbon-counters and trash-littered desks and dust-covered law books."

Current Comment

The problems which face organized medicine, have been heard on the stage, over the radio, and on the platform of formal debate. It is delightfully unfolded now in a novel by Allen Hart, entitled "Dr. Mallory." While no opinion is here expressed as to the views presented in the book, the following comment by the leading character is informative: "I guess I'm a conservative radical. Anyhow, I want to hang on to the ideals of our profession, use them for guides. I'm not afraid of state medicine, but I'm not sure it's the solution for our troubles either . . . Let's not throw away our old galluses, until we see how dependable the new-fangled braces will be."

There has been formed in New York City an *Interne Council*, which publishes a paper called, *The Interne*. Among its basic aims are the following: Improvement of educational, laboratory and living facilities at the various New York hospitals; securing the passage of legislation providing for the insurance of internes injured, disabled or dying in the course of duty; securing eventually, compensation for internes; to facilitate inter-hospital activities of a clinical and possibly of a social and recreational nature; to foster conferences, seminars, and other educational programs of primary interne interests; to establish a central interne organization which might effectively represent interne affairs, and so forth. Organized medicine should be proud to welcome its future leaders in this, their early endeavors. It is a step in the right direction.

Another evil of Panel Practice is disturbing England. Now it seems that the British Medical Association is investigating an evil that has sprung up in the north of England, where physicians have been buying panel practices by mortgaging them to money lenders. This, of course, gives the money lender a financial interest in the practice, and a hold on the doctor. The London correspondent of the *Journal of the A. M. A.* says that in some parts of the north of England it is difficult to purchase a practice from a physician, because the financial corporations get in first and offer cash down. They also circulate newly qualified men, pointing out how easy it is to purchase a practice as they provide the money. The procedure has a bad influence on the efficiency of the service. The financial corporations make tempting offers to sellers, and therefore, impose onerous conditions on buyers, who may have difficulty in fulfilling their obliga-

tions and resort to canvassing and the easy issue of certificate in order to get patients.

The English are trying now to frame a scheme with a medical insurance agency for the purchase of practices whereby reasonable security being afforded, the whole of the money might be provided under terms not too onerous or likely to commercialize the practice.

Although short wave therapy has been known in England for many years, it is a new process in the United States. It is important that the medical profession become acquainted with this field of therapy.

Short wave therapy is a form of radiation, the rays differing from X-ray and gamma rays in their length. It is alleged to be superior to diathermia. It can be used in acute infections where diathermia is contra-indicated. Physicians should study this subject carefully from proper professional sources, and reject information from lay physiotherapists, quacks, and cultists.

In a recent address, Dr. S. S. Goldwater said among other things: "My idea of a hospital is one run from the inside . . . If political pressure or powerful opinion is exerted from the outside, the hospital and the profession of medicine are bound to suffer . . . One-half of the City's population [New York City] since the depression, has looked to the public hospitals for care."

Among the various schemes to bring patients and doctors together and provide means for paying for the service, is a new plan which has been proposed by Dr. Caldwell B. Esselstyn, and analyzed by a subcommittee of the Committee on Economics of the Medical Society of the County of New York. It is essentially a plan of group medicine, advocated for incomes up to \$15,000 annually. The plan was not approved.

Dr. Edward H. Ochener of Chicago, writing in the *Medical Record* of March, 1935, says that he has been "*viewing with alarm* the reckless, and what seemed to me, uncalled for coining of new words. . . . It has almost come to the point that a specialist in one of the branches of the healing art is unable to understand a fellow practitioner in another medical specialty. . . . This tendency is especially dangerous because no man can become or remain a really competent specialist, or even general practitioner, who does

County Societies

Albany County

The following committees to handle the work of the Albany County Medical Society have been announced by Dr. Walter A. Reynolds, President. The first named in each case is chairman:

Program: Dr. E. E. Hinman, Dr. Erastus Corning, Dr. W. P. Howard, Dr. A. VanderVeer, Dr. Harold Peck. Legislative: Dr. Joseph Lawrence, Dr. J. F. Rooney, Dr. F. C. Conway. Public health: Dr. Otto Faust, Dr. D. V. O'Leary, Dr. F. W. Dodge. Economics: Dr. John Gutman, Dr. Charles K. Winne, Dr. C. A. Traver. Physiotherapy: Dr. J. W. Ghormley, Dr. P. L. Forster, Dr. Milton Aronowitz. Public relations: Dr. Joseph Kiernan, Dr. I. J. Murnane, Dr. L. A. Sutton, Dr. Louis Hacker, Dr. J. F. Mosher. Press relations: Dr. Arthur W. Wright, Dr. A. L. Madden, Dr. Albert VanderVeer, 3rd, Dr. M. O. Barrett, Dr. Robert Faust. Cancer: Dr. C. F. Graham, Dr. John Heslin, Dr. A. J. Wallingford.

Broome County

Deploring medical information placed before the public for commercial purposes, the Broome County Medical Society is planning a campaign to educate the people on medical matters.

The educational program covers a wide range of subjects, the outstanding one being health insurance. Other constructive medical subjects are being prepared.

Erie County

The proper medical education of the public will rid us of many of the evils that now plague the medical profession, declared Dr. Herbert H. Bauckus in his presidential address before the Medical Society of the County of Erie on January 21. "Education," he said, "will place the proper stamp upon quackery and nostrums, unnecessary and poisonous drugs, exaggerated radio advertising, cults and fadists, illegitimate practitioners, and in general all schemes cruelly making fear and credulity tools for financial gain. The financial, physical and mental cost of these is appalling. Education will serve to make more useful citizens of those now opposed to the applications of scientific facts in our public health administrations,—if these persons would read the unbiased history of tuberculosis, smallpox, diphtheria, typhoid fever, typhus fever, yellow fever, malaria, bubonic plague, in fact any disease, few of them would longer revile our public health laws. The same history will convince

one of the great value of post mortem examinations and the absolute necessity of animal experimentation. This education is largely our duty and problem. In this we need the aid of every educational institution from the kindergarten to the college."

Kings County

"Alumni Day" of the Long Island College of Medicine will be celebrated on Saturday, April 27, with the following program:

11:00 A.M.: Clinical Hall, Polhemus Building—"Modern Treatment of Syphilis," Dr. Paul O'Leary (Cl. '15), Professor of Dermatology, Mayo Clinic; Discussion by Drs. Alfred Potter, Luther F. Warren and Thurman Givan.

1:00 P.M.: Luncheon at Long Island College Hospital, Main Dining Room (Courtesy of the Hospital)—Speaker, Dr. Henry Wallace (Cl. '90), "Memoirs of an Old Timer."

8:00 P.M.: Annual Alumni Banquet, Knights of Columbus Building, 1 Prospect Park West, Brooklyn N. Y.—Speaker of the evening, Dr. William A. White (Cl. '91), Professor of Mental and Nervous Diseases, St. Elizabeth Hospital, Washington, D. C.

Dr. John J. Black was re-elected president of the North Brooklyn Medical Society at the annual election of officers. Other officers are: Dr. Samson Seeley, vice-president; Dr. William F. Walenta, recording secretary; Dr. Vladimir Smith, corresponding secretary; and Dr. William Haupt, treasurer.

More than 500 persons prominent in medical, military, and political life attended a dinner at the Hotel St. George, Brooklyn, in honor of Dr. Philip Goldstein, chief surgeon of the Harbor Hospital, attending surgeon at Coney Island Hospital, and Captain in the 105th Field Artillery.

A silver flatware dinner service and tray were presented to him. The dinner was in recognition of Dr. Goldstein's service in philanthropic, patriotic, and medical fields.

Uncompromising views on medical ethics are held by Dr. J. Sturdivant Read, the new president of the Kings County Medical Society. The medical society is the group which should protect the people from fee-splitting and other shady practices, he holds. He said further in a press interview: "Publicity has been responsible for many misunderstandings of and violations of medical ethics. The case

of Dr. Dafeo, who was feted recently for his work with the quintuplets, is of special interest because he showed good taste throughout the ordeal of publicity.

"Good taste or background is valuable in my profession, as it marks the distinction between a professional man and a business man. The latter, quite rightly, seeks to gain the most profit from any deal. But this should not be so with the doctor. He must always remember that his patients are in no humor to bargain. During the past twenty years the medical profession in this country has admitted many who do not understand this viewpoint."

Monroe County

Joseph P. MacSweeney, chairman of the Rochester Committee of the Tuberculosis and Health Association, on February 16 announced the appointment of Dr. John J. Lloyd and E. R. Stonaker to head the subcommittees on tuberculosis service and health education, respectively.

He also announced the re-establishment of a health education service in parochial schools, discontinued some time ago on account of fund shortage.

Other activities discussed included health examination promotion in co-operation with the Chamber of Commerce, an early diagnosis campaign sponsored by the Medical Society of the County of Monroe, and maintenance of a demonstration and exhibit service in the public schools with the co-operation of the Department of Health Education and the Health Bureau.

Dr. George G. Carroll was elected president of the staff of the Park Avenue Hospital in Rochester on February 14 at a meeting of the board of directors and staff at the Rochester Club.

New York County

Commissioner Goldwater has named Miss Irene Robertson director of nursing to succeed Miss Marian Rottman, resigned. The director's office will be moved from Bellevue Hospital to the central office of the department in the Municipal Building.

The appointment of Dr. Adam Eberle as acting general medical superintendent was also announced. Dr. Edward Bernecker, medical superintendent of the Metropolitan Hospital on Welfare Island, takes Dr. Eberle's place as medical superintendent at Kings County Hospital. Dr. Chrisman Scherf, superintendent at the Sea View Hospital, goes to Metropolitan Hospital, and Dr. Morris Jacobs, deputy medical superintendent at City Hospital, becomes acting superintendent at Sea View. Dr. Goldwater also announced the appointment of Dr. Charles

S. B. Cassassa as surgical director at Harlem Hospital.

Dropping of useless positions in the municipal hospitals during 1935 has already saved the city more than \$500,000.

Is smoking an etiological factor in peptic ulcer? Some have supposed so, but New York City figures reveal that during the past ten years, during which the proportion of women smokers has undoubtedly increased, there was a decline in the mortality of peptic ulcer among females. Statistics of deaths from cancer of the buccal cavity, too, fail to show any increased mortality since smoking among women has become more prevalent. In studying peptic ulcer it is interesting to note that during the past twenty years there has been a definite decline in the death rate among females while the death rate in males has increased markedly.

Here is a tragic lesson for parents: During the past three and one-half years 538 deaths of diphtheria were registered in New York City. Of this number 22 occurred in children who had received protective injections of toxin-antitoxin or toxoid, and 516 who had not received any protective injections.

How Federal officials spare fees is told in a letter from an ophthalmologist printed in the *New York Medical Week*. The case "was that of a traumatic cataract in which beginning infection was present. The patient was treated by me until infection was under control; the cataract was then operated upon, and normal vision resulted. The treatment lasted for over two months and included the original examination, sixteen office visits, operation for cataract and nine visits at the hospital. For these services after seven months I received a check for \$97.25 from Washington."

Agreement to drop the old 12-hour day for special duty nurses and to adopt the 8-hour day instead has been reached in 34 hospitals in New York City, compared with 21 a year ago, according to a report made public by the Committee on 8 Hours for Nurses.

To facilitate the placing of needy dependents, a survey of hospitalization in the city's five boroughs is being made by the Physicians' Wives' League of Greater New York.

Onondaga County

Group hospitalization for Syracuse moved one step nearer realization when five representative committees meeting on February 13 authorized the appointment of an advisory committee of 27 empowered to study plans.

The committees represented at the meeting included those from the health and hospital division of the chest and council, Central Trades and Labor Assembly, chamber of commerce, Onondaga County Medical Association and Syracuse Academy of Medicine.

Queens County

A keen thrust at the radio medical quacks and other such charlatans was delivered by Dr. Morris S. Bender in his inaugural address as President of the Queens County Medical Society. "If the people correctly understood the fixed causes of disease and how to avert them," he declared, "they would require a strong system of measures to effectively rid the Nation and the State of charlatanism, quackery, and the exploitation of health by manufacturers of nostrums whose advertisements are belched forth by glib-tongued radio orators and pseudo-scientists, whose words of wisdom on pink tooth brush, halitosis, and faulty elimination are so inspiring. How much health and how many lives are sacrificed to this greed for profit?"

The Plan and Scope Committee of the Queens County Medical Society announces plans for an elaborate Bazaar and Medical Exposition to be held in the Society Building from April 6 to 13, inclusive.

Many interesting innovations are to be presented. Special arrangements have been made to offer a new and unusual floor show every night. The exposition will provide opportunity to become acquainted with the talents of the Society's gifted members; of the many works of art, science, and handicraft to be exhibited, a considerable number will be the actual work of local members of the medical profession.

Merchandise of modernistic design has been received for display in the various booths. This bazaar will be the second to be held in the Society's building. The first was held at the official opening in December, 1930, and was very successful.

A beautiful Oldsmobile sedan is to be awarded to the winner of the door prize. Several other equally valuable prizes are to be awarded to the winners of the contests to be held, including a Ford sedan, or its equivalent, to the most successful lady contestant. All prizes and awards are to be distributed by the committee in charge and are not limited to members of the medical profession.

The Women's Auxiliary to the Queens County Medical Society voted an appropriation of \$200 to furnish a committee room for the doctors in the Medical Society Building, 112-25 Queens boulevard, Forest Hills.

Rensselaer County

Edward M. Wells, Jr., was elected president of the medical staff of the Leonard Hospital at the annual meeting held in the Hendrick Hudson Hotel, Troy, February 9. Dr. John F. Connor was named vice-president, and Dr. Mario J. Cuoco, secretary-treasurer.

Rockland County

Dr. James W. Smith has been appointed consulting ophthalmologist to the Nyack Hospital, Nyack.

Washington County

Dr. Harley Heath, 53, of Comstock, chief physician at Great Meadow Prison since it was built about twenty-four years ago, died February 12 at his home after a heart attack which followed two weeks' illness with a cold.

Westchester County

The proposal to establish a collection agency under the supervision of the County Medical Society has been referred to the Economic Committee for study. This matter was discussed at the last meeting: a final report will be submitted when the preliminary work has been completed. The committee remarks in the county *Medical Bulletin* that it is "very doubtful" if such an agency "would be an effective substitute for that which doctors in general fail to do themselves."

The County Medical Society is organizing a speakers bureau service, to be offered to service clubs, women's clubs, church groups, P. T. A. chapters, study groups, chambers of commerce, etc., throughout the County. This service is to be announced both in the papers, and directly to the organizations which will find it useful. These groups will be invited to communicate with the Executive Office of the Society when speakers are desired on any topics in the realm of medicine, public health, or medical economics. The Executive Office will keep a cross-index file of speakers and the subjects they have volunteered to speak on. An announcement says:

"Speakers are needed. If you are willing to assist the Society in this important work, please notify the Society, listing the general topics, or if possible, specific titles upon which you are prepared to speak before lay groups. If you are interested in a certain topic, but desire a bibliography on it to assist you in further preparation, please so indicate."

Dr. James A. Tobey, of Rye, was elected president of the Westchester Tuberculosis and Public Health Association at the annual meeting of the executive committee.

LORENZ J. BROSNAN, Esq

Counsel, Medical Society of the State of New York

Autopsies in Cases of Suspicious Deaths

Recently in one of the Mid western States, a case* came before the courts in which the right of a coroner to perform an autopsy in a case of suspicious or accidental death, was challenged.

A married man was found by his wife, sitting apparently dead, behind the wheel of his automobile in the garage. One door of the garage was found partly open. Assistance was summoned, and firemen with a pulmotor, an ambulance physician, and a deputy coroner promptly responded. Attempts to resuscitate the man failed. The deputy coroner, Dr. W., directed an undertaker to take the body to the County morgue, where he ordered another physician, Dr. C., to perform an autopsy. No notice of this order was given to the widow. The autopsy was performed and the findings were that the man had died of monoxide gas poisoning.

The widow upon learning of the performance of the autopsy, brought an action against the undertaker, Dr. W., and Dr. C. to recover damages for wounded feelings. The claim was made that the case was not a proper one to permit a coroner's autopsy, and further, that the autopsy was improperly performed. Upon the trial of the action the plaintiff proved substantially the facts set forth above. She did not, however, offer any competent proof to show that the body was excessively mutilated or that the organs of the deceased were not replaced after examination. So far as appeared from the testimony, the autopsy was performed in the usual customary manner. At the close of the plaintiff's case the defendants moved to dismiss the action relying upon statutory authority for their acts. The Court ordered a directed verdict in favor of the defendants.

It appeared that the statutes of the State in question provided that the coroner of the respective Counties should investigate and issue his death certificate in all cases of "Violent, mysterious and accidental deaths, including suspected homicides." The statute also made it unlawful for the body of such a person to be removed or interfered with except in connection with the coroner's investigation or until its completion.

The plaintiff in the action took an appeal from the Trial Court's ruling and the highest Court of the State affirmed the decision

of the Court below. The Appellate Court conceded that in ordinary cases the widow has the legal right, which the law will protect, to possession of the dead body of her husband for purposes of burial, and that a wrongful mutilation of or interference with the corpse would entitle the wife to damages against the wrongdoer. The Court decided that in the case before it, no wrong was shown and stated in its opinion:

There can be no doubt that Mr. K's death came within the class of deaths the coroner was required by this law to investigate. And for the purposes of such investigation Dr. W. had exclusive control of the body. He could direct the undertaker to carry the body to the county morgue if he deemed it necessary for an investigation. An autopsy may be the surest and most satisfactory way of determining that the death was accidental, and since the statute provides that the coroner "shall order an autopsy when and where he deems proper," the conclusion is inescapable that the coroner may as an aid to his investigation order an autopsy. The coroner is also by law required to make the death certificate necessary, and therein state the cause of death. To do so accurately he may have considered it necessary to have an autopsy. It is true that he may not arbitrarily order an autopsy when a properly made investigation has disclosed to him the cause of the death. It cannot be made to satisfy an idle curiosity, or for the information of some interested insurance company, or to give some doctor a fee, or for a purpose not within the law. The fact that plaintiff was not informed that an autopsy was contemplated (though she knew that the body was taken to the County morgue) does not tend to prove arbitrary exercise of the coroner's discretion.

In this State should a similar situation arise, the ruling of the Courts should be to the same effect. The Penal Law (Sec. 2213) provides that the right to dissect the dead body of a human being exists:

Whenever a coroner is authorized by law to hold an inquest upon a body, so far as such coroner authorizes dissection for the purposes of the inquest, and no further,

The Code of Criminal Procedure (Sec. 773) provides as follows:

Whenever a coroner is informed that a person has been killed or dangerously wounded by another or has suddenly died under such circumstances as to afford a reasonable ground to suspect that his death has been occasioned by

* *Kingsley v. Forsyth* 257 N.W. 95

criminal means, or has committed suicide, he must go to the place where the person is and forthwith inquire into the cause of the death, or wounding, . . .

In an informal opinion handed down by the Attorney-General a few years ago, the extent of the permission granted to coroners under the law was interpreted as follows:

A coroner is justified in ordering an autopsy if he deems the same necessary for the purpose of obtaining evidence as to the cause of death or the manner in which death was inflicted.

The Public Health Law contains the following provision in connection with violent deaths (Sec. 378):

In case of any death occurring without medical attendance, it shall be the duty of the undertaker or other person to whose knowledge the death may come to notify the local health officer of such death, and when so notified the health officer shall immediately investigate and certify as to the cause of death; provided that if the health officer has reason to believe that the death may have been due to unlawful act or neglect he shall then refer the case to the coroner or other proper officer for his investigation and certification.

It would seem from said provision that a health officer is not ordinarily empowered to perform an autopsy without consent from the deceased's relatives and next of kin, but if he feels a crime has been committed it becomes his duty to notify the coroner, who has power to hold an autopsy regardless of the consent of the relatives and next of kin of the deceased person.

As to the City of New York, the Greater New York Charter contains special provisions whereby a medical examiner is authorized to take charge of investigating violent and suspicious deaths and to perform autopsies in proper cases. Sections 1571 and 1571-a of the Charter provide in part as follows:

When, in the city of New York, any person shall die from criminal violence, or by a casualty, or by suicide, or suddenly when in apparent health, or when unattended by a physician, or in prison, or in any suspicious or unusual manner, the officer in charge of the station house in the police precinct in which such person died shall immediately notify the office of the chief medical examiner of the known facts concerning the time, place, manner and circumstances of such death. Immediately upon receipt of such notification the chief medical examiner, or a deputy or assistant medical examiner shall go to the dead body, and take charge of the same. Such examiner shall fully investigate the essential facts concerning the circumstances of the death, . . . If the cause of such death shall be established beyond a reasonable doubt, the medical examiner in charge shall so report to his office. If, however, in the opinion of such medical examiner, an autopsy is necessary, the same shall be performed by a medical examiner. A detailed

description of the findings written during the progress of such autopsy and the conclusions drawn therefrom shall thereupon be filed in his office.

Treatment of Injured Wrist

A woman about fifty years of age, complaining of an injured wrist, called a doctor who specialized in surgery, to her home. The doctor learned that she had been engaged in some sort of an argument with a man who had grabbed her right wrist and twisted it, causing it to severely pain her. The doctor immediately applied an emergency splint and suggested hot applications and sent her the same day to the office of a nearby x-ray specialist to have x-ray plates taken. The report which was made on the x-ray plates showed that the wrist was normal and negative for any fracture or dislocation. The doctor after receiving the said report again examined the patient and found apparently no deformity other than swelling and undertook to treat the injury as a sprain.

The doctor next saw her about ten days later and at that time the wrist was still swollen but not so badly as it had been before. He told the patient to continue hot applications and to return to his office in about a week. The patient did not return and he heard nothing further about the matter until approximately two years after the occurrence, when the patient came in and exhibited her wrist. She, at that time, had with her an x-ray plate that had been taken a short time before. The patient's wrist then was somewhat deformed and the use of her fingers seemed to be limited. The doctor did not treat her but suggested she return to the doctor who had been caring for her and at whose request the x-ray that she exhibited had been taken. Within a few days after the said visit, papers were served upon the doctor commencing a malpractice action in which it was charged the doctor had improperly treated the injury and had caused her to sustain a result which constituted loss of function of the hand.

Investigation showed that at no time had any diagnosis of fracture or dislocation been made by any doctor; that shortly after she was treated by the defendant she went to another doctor who had put the wrist up in a splint for about six weeks. After the said treatment she had apparently neglected the condition for a considerable period of time and a deformity had developed as a result of which the plaintiff carried her hand flexed at an angle about 30 degrees from normal and that she had become unable to use the wrist or fingers to any extent. The case came up for trial before a judge and jury and during the second day of the trial the plaintiff's attorney apparently realizing that he was un-

able to prove his cause of action against the defendant doctor, discontinued the action.

Death Following Taking of Pill Containing Strychnine

A woman about sixty years of age called a physician in general practice to her home, and upon examination he found her to be complaining of a severe cough and suffering from chronic myocarditis, nephritis, and bronchitis. He gave her various medicines for her condition and saw her for several consecutive days. At the end of that time the doctor found the patient's heart condition was not satisfactory and wrote out a prescription for certain tablets, each to contain 1/30th of a grain of strychnine sulphate. Later the same day he was called to the patient's home and found that she was in bed suffering from cramps of the muscles of the backs of the legs. He was informed she had taken one of the tablets which he prescribed. The doctor suspected an overdose of strychnine and upon investigation found

that the druggist had made a mistake and instead of filling the prescription properly, he had put one grain of strychnine into each tablet. The doctor gave the patient emetics and she apparently responded to the treatment and seemed to improve. However she passed away the second day after she had taken the medicine.

An autopsy which was performed, failed to reveal that the overdose of strychnine had hastened the death of the patient for the findings indicated that the actual cause of death was heart disease.

An action was brought by the patient's administrator against the doctor, to which the druggist was also a party, in which the claim was made that the doctor was negligent in improperly prescribing for his patient and as a result of said claim of negligence, the patient died. Plaintiff's attorney never brought the case on for trial and after some time had elapsed an application was made to the Court on behalf of the defendant to dismiss the complaint, and the court ordered the dismissal of the action so far as the doctor was concerned.

MISLEADING DENTAL ADVERTISING

Some of the exaggerated claims made for dental preparations in the advertisements are given a dose of common sense by Dr. W. M. Gardner in *Hygeia*. For instance, we are assured in the ads that alkaline dentifrices will neutralize mouth acids and make them harmless, but the fact is that the decay is caused by "spot" acidity, a little acid factory protected by a mucin film which the dentifrice cannot penetrate. It takes the stiff bristles of the brush to break through this film, and even then the saliva can do the work of dilution and neutralization without the aid of an alkaline dentifrice. Antiseptics and germicides in dentifrice fail in the same way. Dr. Gardner also tells us that medicines and drugs in dentifrice are of no value, for they cannot prevent or cure pyorrhea or other gum diseases.

Neither is a mouth wash a therapeutic agent for diseased gum tissue, he adds, and recommends as the safest and cheapest mouth washes the following: warm water; a normal salt solution made by adding 1 teaspoonful of salt to 1 pint of water; a normal salt solution to which a pinch of baking soda, sodium bicarbonate, or borax has been added.

The curative power of mouth washes on gum tissue has been grossly overestimated. Mouth washes are ineffective in the chronic case of pyorrhea usually seen, neither checking nor curing the disease. The problem in successful treatment of pyorrhea is primarily the removal of all things that irritate the gum tissue, such as tartar deposits and faulty dentistry, and the bringing about of an active blood exchange in the gums by means of massage with a toothbrush.

It is well known, of course, that mouth washes cannot correct faulty dentistry. Mouth washes are also ineffective in stimulating gum tissue,

being quite incapable of bringing blood to the areas involved; many mouth washes contain astringents which tend to keep the blood from coming into the area.

Mouth washes that are sold as pyorrhea cures are usually advertised as germ killers, and no doubt some of them are, if they are held in the mouth for a sufficient length of time. But germs are merely secondary factors in pyorrhea, entering the gums only after a lesion has developed from irritations. The bacteria normally found in a healthy mouth are as incapable of producing disease as are the bacteria on the palm of the hand. In both instances, a break in the tissue is a prerequisite of infection.

Proprietary mouth washes, irrespective of their claims, should be regarded merely as pleasantly flavored solutions for mouth toilet, quite on a par with such other toilet articles as talcum powder, toilet waters, and perfumes. There can be little objection to their use if they contain ingredients that are harmless.

Bellevue Hospital recently acquired a new problem in diet in the form of a sidewalk showman whose stock in trade is a demonstration to passersby of his ability to swallow razor blades, pins and ground glass, says *Health Digest*. When arrested he protested, "You're interfering with the NRA—arresting me is restraint of trade—I earn my living this way." Magistrate Harris summed up the situation differently by saying, "Roughage may be excellent for the health but such meals are undoubtedly not what the doctor ordered." The showman is now safely in the observation ward.

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Body Mechanics in the Study and Treatment of Disease. By Joel E. Goldthwait, M.D. et al. Octavo of 281 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1934. Cloth, \$4.00.

Sculpture in the Living. Rebuilding the Face and Form by Plastic Surgery. By Jacques W. Maliniak, M.D. Octavo of 203 pages, illustrated. New York, The Lancet Press, 1934. Cloth, \$3.00.

The Physical and Mental Growth of Prematurely Born Children. By Julius H. Hess, M.D. et al. Octavo of 449 pages. Chicago, University of Chicago Press, [c. 1934]. Cloth, \$5.00.

Salt, Water and Health. By Frederick Hoelzel. Nar. Octavo of 32 pages. Chicago, Frederick Hoelzel, 1934. Paper 50 cents.

Outlines for Psychiatric Examinations. Edited by Clarence O. Cheney, M.D. Octavo of 134 pages. Utica, N. Y., State Hospitals Press, 1934. Cloth, \$1.50.

Standard Classified Nomenclature of Disease. Compiled by the National Conference on Nomenclature of Disease. Edited by H. B. Logie, M.D. Duodecimo of 870 pages. New York, The Commonwealth fund, 1935. Cloth, \$3.50.

Franklin Paine Mall. The story of a Mind. By Florence Rena Sabin. Octavo of 342 pages, illustrated. Baltimore, Johns Hopkins Press, 1934. Cloth, \$2.75.

A Brief Outline of Modern Treatment of Fractures. By H. Waldo Spiers, M.D. Octavo of 129 pages, illustrated. Baltimore, William Wood & Co., 1935. Cloth, \$2.00.

The Surgery of the Sympathetic Nervous System. By George E. Gask and J. Paterson Ross. Quarto of 165 pages, illustrated. Baltimore, William Wood & Co., 1934. Cloth, \$4.00.

Aids to Embryology. By Richard H. Hunter, M.D. Second Edition. Sexdecimo of 172 pages, illustrated. Baltimore, William Wood & Co., 1934. Cloth, \$1.25.

Aids to Psychiatry. By W. S. Dawson. Third Edition. Sexdecimo of 318 pages. Baltimore, William Wood & Co., 1934. Cloth, \$1.50.

The Crippled and the Disabled. Rehabilitation of the Physically Handicapped in the United States. By Henry H. Kessler. Octavo of 337 pages. New York, Columbia University Press, 1935. Cloth, \$4.00.

Human Anatomy, Double Dissection Method. By Dudley J. Morton. First and Second Dissections. Quarto of 265 pages, illustrated. New York, Columbia University Press, 1934. Cloth, \$6.00.

Stammering and Allied Disorders. By C. S. Bluemel, M.D. Duodecimo of 182 pages. New York, Macmillan Co., 1935. Cloth, \$2.00.

Rats, Lice and History. Being a Study in Biography, which, after Twelve Preliminary Chapters Indispensable for the Preparation of the Lay Reader, Deals with the Life History of Typhus Fever. Octavo of 301 pages. Boston, Little, Brown & Co., 1935. Cloth, \$2.75.

Modern Operative Surgery. Edited by G. Grey Turner, F.A.C.S. Second Edition in two volumes. Octavo of 1760 pages, illustrated. Baltimore, William Wood & Co., 1934. Cloth, \$16.00.

A Synopsis of Surgical Anatomy. By Alexander Lee McGregor, F.R.C.S. Second edition. Duodecimo of 644 pages, illustrated. Baltimore, William Wood & Co., 1934. Cloth, \$6.00.

Infantile Paralysis. By George Draper, M.D. Octavo of 167 pages. New York, D. Appleton-Century Co., 1935. Cloth, \$2.00.

How to Practice Medicine. By Henry W. Kemp, M.D. Octavo of 158 pages. New York, Paul B. Hoeber, Inc., 1935. Cloth, \$2.50.

One Hundred and Fifty Years of Publishing 1785-1935. Octavo of 42 pages, illustrated. Philadelphia, Lea & Febiger, 1935.

Alcohol and Anaesthesia. By W. Burrige, D.M. Octavo of 65 pages. London, Williams & Norgate, Ltd., 1934. Cloth 2/6.

Oedemes et Congestions Pulmonaires. By Drs. G. Caussade & André Tardieu. Duodecimo of 266 pages, illustrated. Paris, Félix Alcan, 1934. Paper 25 francs.

A Synopsis of Medicine. By Henry Letheby Tidy, M.D. Sixth edition, Revised and enlarged. Duodecimo of 1112 pages. Baltimore, William Wood & Co., 1934. Cloth, \$6.00.

System of Diet Writing. Including Diet Calculator, Obesity Chart, Diet Formulary, 100 Menu Prescription Forms. By William S. Collens, M.D. New York, Form Publishing Co., [c. 1933]. Cloth, \$5.00. Oblong 16mo. of 142 pages.

Disease; Gadfly of the Mind. By Wm. Allen Pusey, M.D. Octavo of 20 pages. London, H. K. Lewis & Co., 1934.

Hughes' Practice of Medicine. Revised and Edited by Burgess Gordon, M.D. 15th ed. Duodecimo of 808 pages illustrated. Philadelphia, P. Blakiston's Son, [c. 1935]. Cloth, \$5.00.

The Medical Clinics of North America. Vol. 18, No. 3. November, 1934. (New York Number) Octavo. Published every other month by the W. B. Saunders Co., Philadelphia. Per Clinic year (6 issues). Cloth, \$16.00; Paper, \$10.00.

REVIEWED

Manual of the Diseases of the Eye. For Students and General Practitioners. By Charles H. May, M.D. Fourteenth Edition. Octavo of 496 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$4.00.

If Fuchs' textbook is the Ophthalmologists' bible this little volume surely should be called his testament. Full of meat as a nut it is kept fresh and modern by frequent editions, and is a thoroughly reliable and instructive manual.

In the present edition sufficient changes in the text have been made to bring it up to date and two new colored plates added, one illustrating detachment of the retina with a tear. The chapter on retinal detachment is characteristic of the book—a concise, restrained and thoroughly modern description of this interesting condition and its treatment.

E. CLIFFORD PLACE

The Spastic Child. By Marguerite K. Fischel. 12mo. of 97 pages, illustrated. St. Louis, C. V. Mosby Company, 1934. Cloth, \$1.50.

The writing of this little work was urged by the late Dr. Nathaniel Allison, the well known orthopedist. He suggested to the writer, the mother of two boys, who were victims of spastic paraplegia (Little's disease), to pass along her methods of re-education of muscles to other such victims.

We believe there is certainly no more pitiable deformity to behold and certainly no more difficult one to treat than this class of cases.

The foundation of her work is fundamentally one of great patience and much hard work. The book contains the etiology, speech correction, physiotherapy, and orthopedic mechanical aids, not overlooking the guidance of this type of child in school work, home surroundings, sports, and the social problems encountered. The methods employed finally restore the adult spastic to his citizenship and a useful place in his community.

JOSEPH I. NEVINS

The Power to Love. By Edwin W. Hirsch, M.D. Octavo of 363 pages, illustrated. New York, Alfred A. Knopf, 1934. Cloth, \$4.00.

Love, according to most medical writers, implies solely the gratification of physical pleasures in both the male and female. According to that theory, free-love based on illicit sexual relationships should mean the ideal love; and liberal divorces and companionate marriages should be justified for the attainment of love.

Admiration, affection, loyalty, devotion, romance, mutual comfort, and friendship seem to play no part in the author's conception of love. Love signifies solely an anatomical attraction, something possessed especially by the young adult. And as we unfold the covers of this book, we hardly find mention

of even the word "love," but we read of sexual debility, frigidity, premature ejaculation, sexual fear, and of all the other disturbances which cast a pall on the sexual act. The information is readable and follows the routine adopted in other popular books on sex.

While the title, "*Power to Love*," seems appealing to the lovelorn reader, the caption, "*Power to Copulate*," would seem to fit in with the textual reading.

EMANUEL KRIMSKY

Papers of Charles V. Chapin, M.D. A Review of Public Health Realities. Selected by Frederic P. Gorham, Sc.D. Edited by Clarence L. Scamman, M.D. Octavo of 244 pages. New York, The Commonwealth Fund. Cloth, \$1.50.

This book presents sixteen of the papers written by Dr. Charles Value Chapin and selected as representative of the contributions he has made in the fields of public health administration, communicable disease control, epidemiology, and vital statistics.

It should be tremendously interesting and stimulating to all students of the development of modern public health methods. Through the eyes of this outstanding leader, we see in outline the advances made in the public health field during half a century.

Notable among the sixteen chapters are those on studies in air and contact infection, quantitative methods in epidemiological work, and on the principles of epidemiology, as well as the chapter which considers the changes in the type of contagious diseases.

In these papers we see clearly the viewpoint of this pioneer in public health and preventive medicine, this public health officer, with his common sense and practical, logical and scientific mind, with his precision of method and honesty of thought and purpose, and his never failing courage in upholding the truth—the truth which he so often so studiously and with such great tenacity work to bring to light and which he had in many instances the almost prophetic vision to see. Dr. Chapin's life and work provide an outstanding example, in our times, of the finest traditions of the medical profession and of inspiring leadership. Here is a record of rare accomplishment by a public official who ever considered his public office—a most of honor and a sacred trust—in which he could well serve humanity by giving the utmost measure of service from a keen intellect.

JOSEPH C. REGAN

Practical Talks on Heart Disease. By George L. Carlisle, M.D. Octavo of 153 pages. Springfield, Ill. [c.1934]. Cloth, \$2.00.

In simple, conversational language, Carlisle presents a series of talks, covering in 140

pages the subject of heart disease, from history taking to cardiac neuroses. The book is intended for the "general practitioner," but it will hardly satisfy the physician who is keenly interested in his work, for it conspicuously lacks the qualities of thoroughness and depth. Space is not used to best advantage. A terse direct style would have permitted adequate and more scientific presentation of the subjects considered.

The author is emphatic in his disposal of "mitral regurgitation," accomplishing it with one sweep of the broad-sword, and burying its remains. This reveals an interesting and forceful individual point of view, but what shall we say when on page 73 he discusses the soft systolic murmur of "mitral leak" in acute rheumatic heart disease?

Is it not, forsooth, high time that mitral regurgitation should be recognized for what it is, with its triad of criteria in diagnosis:

the murmur, the moderate enlargement of the heart, and the accentuation of the second pulmonic sound! We should think of it as due either to dilation of the orifice or to defect of the valve. If rheumatic fever has damaged the valve, a certain sequence of events is to be expected and we will eventually look for the development of mitral stenosis (found always at the autopsy of cases dying with mitral rheumatic heart disease) but we must not expect to find stenosis from the beginning of the valvular involvement. Much pathological experience supports this opinion. In the early stage of mitral disease therefore, we should recognize that mitral regurgitation may be definitely present and that it is a reality.

"Myocarditis" as a term in diagnosis assuredly requires modification and definition. With the author's statement, the reviewer is in full sympathy. FRANK BETHEL CROSS

NEW HEALTH RECORDS FOR NEW YORK CITY

Despite the unfavorable influences of the economic depression, New York City established several new records in health during 1934, says the *A.M.A. Journal*. The general death rate was 10.15 per thousand of population, the lowest in the history of the city; the actual number of deaths was 75,857. The greatest number of deaths (30,948) occurred in the group of diseases of the heart, arteries, and kidneys, including cerebral hemorrhage. Tuberculosis, which has steadily decreased in the last ten years, caused 3,950 deaths, a rate of 52.85 per hundred thousand.

This result, a new low point, was attributed to efficient organization of relief and to intensified control activities, such as improved x-ray equipment, extension of facilities for pneumothorax treatment, and better follow up of cases. The pneumonia death rate in 1934 was the lowest on record, but this was partly attributed to the low prevalence of measles and the absence of an influenza epidemic. Fewer cases of diphtheria were reported to the health department than in 1933, but deaths increased from 86 to 103, indicating a more severe type of the disease, according to the report. The death rate from whooping cough declined from 25.7 in 1933 to 21.99 per hundred thousand of population under 5 years of age in 1934. Only 76 cases of poliomyelitis were reported, with 12 deaths. There were 44 deaths from typhoid, a rate of 0.59 per hundred thousand of population, new low records. The cancer death rate has again increased, being 127.1 as compared with 121.6 in 1933.

The health department has endeavored to focus attention on diabetes as a health problem but, as it is not a reportable disease, figures on its prevalence are not available. The registered death rate rose in 1934 to 30.3

from 29.1 in 1933, but this is believed to be due to the aging of the city's population and to more frequent recognition of the disease. Appendicitis mortality was lower than at any time in the last five years, 13.45 as compared with 15.64 in 1934 and 16.32 in 1931. The death rate from automobile accidents declined from 15.45 in 1933 to 15.28 in 1934; the rate in 1930 was 18.53. The suicide death rate, which began to increase in 1929, reached its highest point (22.1) in 1932 and in 1934 decreased to 16.43. The infant mortality rate in 1934 was 52.22 per thousand births, a reduction from 1933, but not so low as the 1932 rate, 50.91. The birth rate continued to drop, being 13.55 per thousand of population in comparison with 17.64 in 1930. During the past year the department has designated certain "sore spots" on which it is concentrating its activity.

Evidence that leprosy may be spread by healthy, unsuspected carriers of the infection, has been reported by Dr. N. E. Wayson, director of the Leprosy Investigation Station at Honolulu, to the United States Public Health Service, notes the *Medical Record*. Just as with typhoid fever and diphtheria, persons may be infected with the bacillus of leprosy and remain well for a long time, if not for the rest of their lives.

It was found over a period of years in the careful examination of children of leprosy parents that the disease was attacking them. There was definite evidence of this in the condition of their small blood vessels and certain nerves, long before other signs of leprosy could be detected. These evidences could further develop into the disease, or become normal as the years progressed.

New York STATE JOURNAL of Medicine

OFFICIAL ORGAN OF THE
MEDICAL SOCIETY OF THE STATE OF NEW YORK

Vol. 35

APRIL 15, 1935

No. 8

MEDICAL SOCIETY OF THE STATE OF NEW YORK ANNUAL REPORTS, 1934-35

REPORT OF THE PRESIDENT

To the House of Delegates; Gentlemen:

It is my pleasant duty to report to you on the activities of the Society.

District Branches

Fortunately, I was able to attend every District Branch Meeting and to note the keen interest in medicine displayed by those who came to the sessions. In addresses to these groups I referred to some of our statewide services and tried in that way to have them appreciate that their officers were vitally concerned with their personal welfare. All of the meetings were well attended and the scientific papers were of the highest order. It is to be regretted that in some districts where the material for exhibition was most abundant and where there was the greatest concentration of medical men, the attendance was poorest and the participation in district affairs least evident.

County Societies

The County Societies have been active, have held their meetings at regular periods and some have published monthly bulletins.

Committee Meetings

Many meetings of standing committees, the conference of the county secretaries and the gathering of the chairmen of the county legislative committee were attended. The latter two are annual affairs of supreme importance to the practitioners of medicine in this state for they serve to unify and co-ordinate the work of the Society.

On December 20, 1934, there was a special meeting of the members of all standing committees to correlate the busi-

ness of the Society and avoid the friction which was present last year and which was becoming evident in this administration because of overlapping investigations and pronouncements. After a day of open discussion it was the consensus of opinion that there would be less annoyance in the future if each committee would restrict its operations to its own field of endeavor.

The members of the standing committees of the Society are theoretically nominated by the president and elected by the Council. In reality the president has nothing to do with their selection or control over their functions. It would be infinitely better for you, the House of Delegates, to elect them or give the president full power to appoint them.

Standing Committees Reports

The Committee on Scientific Work under the direction of Dr. William A. Groat and the chairmen of the sections has prepared programs which will appeal to every forward looking physician. The subjects chosen are timely.

Dr. James E. Sadlier's Committee on Public Relations has worked with its usual zeal to improve the contacts of physicians and laymen. Its most noteworthy achievement has been to call attention to the pitiable state in which the deaf child is allowed to drift without medical diagnosis or supervision.

The Committee on Economics with the dynamic chairman, Dr. Frederic E. Eliott, will present its voluminous report for your perusal.

Public Health and Medical Education, as you will note from the report of the Chairman, Dr. Thomas P. Farmer, has

been interested in not only supplying the demand for postgraduate courses but also in protecting the physician from further incursions by outside groups. This Committee has always paid the men who have delivered the lectures. As far as I know, no other State Society does this. To have the opportunity of delivering a course of lectures before medical men has always been considered a privilege and no remuneration should be expected. Obviously, expenses should be paid but no honorarium should be given. If this method was established the State Society would save a large sum, the quality of the lectures would in no way suffer and it would be possible to extend the number of courses.

The Committee on Legislation under the guidance of Dr. Harry Aranow has continued to widen its sphere of influence and serve in a devoted way. Even the examination of their detailed reports will not convey an appreciation of the magnitude of their task and a mere formal vote of thanks will not discharge our debt of gratitude to this important committee.

At this time it is impossible to render a report on the vital legislation which is before the New York State Legislature and the National Congress. A supplementary report will be presented at the Annual Meeting.

Dr. Frederic C. Conway and his Committee on Arrangements have made elaborate plans for the housing of the sessions and the entertainment of the members.

Bureau of Public Relations

During the year the Committee on Trends under the chairmanship of Dr. James F. Rooney established the Bureau of Public Relations. Its sphere of usefulness and of influence is almost unlimited, and under the guidance of the wise men who are now in control of that Committee we anticipate a steady improvement in the recognition of medical problems by the laymen, as well as the presentation of authentic information to the members of the Society. The releases sent to the press have been very favorably received. The Bureau will have entire charge of publicity at the annual meeting.

Finance

Treasurer Charles H. Goodrich will report that the Society is financially sound, that so far it has weathered the storm of depression, that the securities are of the highest type, that the members are paying their dues and that the expenses have been carefully controlled.

State Journal

The STATE JOURNAL is improving in appearance, but as I have had a very high ideal for the JOURNAL, I am still disappointed and am more convinced than ever that it is absolutely necessary to employ a full-time editor, and further that the JOURNAL should be under complete State Society control. Such a director would cost little more than the method under which we are now functioning, for I believe that he could be secured for \$6,000, while at the present time we are spending at the rate of more than \$3,600 for part-time service. By regulation of the JOURNAL, we would not have complaints about financial and liquor advertisements which some think most objectionable in a scientific medical publication. There has been a very notable improvement in the reports from County Societies and Medical Notes. There should be more comments on legislative and social security proposals and additional pages devoted to the dissemination of such information rather than abstruse statements which are suggestive of personal opinions not substantiated by experience.

State Department of Education

During the year it has been possible for your officers to establish a cordial relationship with the New York State Assistant Commissioner for Higher Education, Dr. Harlan H. Horner, and as a result of that contact have a fuller appreciation of the problems which confront those who control the licensure of physicians and many of the functions of that department which are so intimately associated with the practice of medicine, including authority over the Grievance Committee.

The Albee Case

It is fitting that you should know that the New York County Medical Society

suspended Dr. Fred H. Albee from membership for a year because of what the members considered to be unprofessional conduct. Dr. Albee appealed to the Board of Censors of the State Society which assembled, listened to legal arguments, and then unanimously upheld the verdict of New York County. At a later time the Executive Committee of the Society, at the request of Dr. Walter T. Dannreuther, the President of the New York County Medical Society, for financial assistance, asked the Board of Trustees to appropriate \$1,500 for expenses contingent upon the continuance of the case in the courts of the State because the Executive Committee felt that the jurisdiction of the State Society had been raised as an issue. It was the understanding of some of us that the money was to be spent in financing an appeal to the higher court. Some of the Executive Committee were disappointed when they read that the case had been closed and that a few days before the termination of the period of suspension Dr. Albee was reinstated to membership in the New York County Society.

He was suspended from the New York Academy of Medicine, June 26, 1934, on charges arising from the same alleged offense. He appealed from the verdict but the Appellate Division of the Supreme Court unanimously upheld the decision of the New York Academy of Medicine.

Nominating Committee

You are conscious that a small self-perpetuating group attempts to control the policies of this Society. They are without delegated authority and I suggest to you that it would be much wiser, and in the long run healthier, for the House of Delegates to elect annually a Nominating Committee to serve for the following year and that no one be permitted to remain on that Committee for more than three consecutive terms. This must not interfere with nominations from the floor and the report of the Committee must be published a month before the session at the time the Annual Reports appear in the JOURNAL. The members should be selected with due regard to their geographical distribution.

Full-Time Executive Secretary

To those who have been in close association with the functions of the Society, there has been an increasing conviction that there should be a full-time executive in charge of the affairs. For efficiency, economy, and the correlation of the infinite activities of the organization, such a change is imperative. When special committees ask for more clerical assistants, for increased appropriations, and for the sanction of new plans, the time for centralization of executive supervision has arrived. The central office should be the source of information, inspiration, and direction. From it every county society should receive suggestions for the improvement of its scientific programs, for its contacts with the innumerable lay organizations which constantly attempt to usurp the powers of the medical profession. Central control would enable those responsible for the conduct of the affairs of the State Society to be in closer touch with those outside of the Society who wish to confer with them, suggest to them, or be instructed by them. The time will come when such a central bureau will be established, for its value has been proven by the experience of many organizations including the American Medical Association. The sooner it is done the better for the medical profession.

Clinical Conferences

From experience in other medical societies, I suggest the inauguration of a new type of State medical education—clinical conferences. This of necessity means the selection of speakers who excel in the treatment of the subject under discussion and who have the ability and the desire to clearly and succinctly place facts before their audience. I would suggest that this innovation be started next year and that the day following the close of the regular meeting be devoted to a series of short lectures and demonstrations so comprehensive in range that they will appeal to every member in the Society and so conveniently scheduled that those who wish can have a complete day of postgraduate instruction. If such a scheme is adopted, I will be very glad to appear before the Committee and go into the elaboration of the plan. By this

method money would be saved, energy conserved, and more members benefited.

Wherever conflict arises between the Constitution and By-Laws and these suggestions, amendments of the former can be made and ratified.

Appreciation

In closing my year, I wish to thank you for the opportunity of serving the Society. I feel as did Dr. Dean Lewis at the expiration of his term as President of the American Medical Association, that: "One must accept such an honor with humility, for one must realize that one cannot discharge efficiently the duties that one assumes and must be called on frequently to make decisions that will not be approved." I have kept free from all semblance of entangling alliances and have refrained from accepting any appointments on the Board of Directors of any other medical or lay association.

It is with pleasure that I acknowledge my indebtedness to all who have helped

to improve the status of the physician and who have assisted in the conduct of the technical affairs of the State Society. It is not possible for me to name each of you individually—the list would be too long—but to every one my personal appreciation is extended, and especially to Dr. Daniel S. Dougherty for his skillful guidance, to Miss L. Baldwin for her enduring tact and comprehension of Society affairs, to Dr. Joseph S. Lawrence for his unfailing co-operation, courtesy, and constant help, the Chairmen and members of the standing and special committees, and our efficient legal counsel, Mr. Lorenz J. Brosnan.

The State Society must accept its responsibility of inspiration and central control so that the efficiency of the physician in administering to the public may be increased and his material interests protected.

Respectfully submitted,

ARTHUR J. BEDELL, *President*

April 1, 1935

REPORT OF THE SECRETARY

To the House of Delegates; Gentlemen:

Your Secretary has the honor of presenting his tenth annual report.

It was with considerable reluctance and misgiving that ten years ago he allowed himself to be elected to this office but he is happy to be able to say that during this time his official and personal relations with the Society and its membership have been of the most friendly and courteous character, and in many instances acquaintanceship has grown into warm friendship.

The Society

The constant and steady growth of the Society in membership and activities has continued during the past year and the increase in knowledge of and interest in these activities speaks well for the soundness and health of this growth. More and more has the membership come to realize the benefits to be accrued only from organized medicine and the necessity of unity and solidarity in thought and action. These attributes are absolutely necessary to resist the warfare that is being constantly waged against us by those both within and without who would

change the character of medical practice and place it under lay and political domination. Your Secretary has in a former report called attention to the dangers of individualism and the over-enthusiasm which often causes thoughtless haste, and these dangers exist just as strongly today.

Although the Society now occupies a more important position and exerts more influence than in former years the necessity of an earnest study of the economic and social problems affecting organized medicine is becoming more and more evident.

The Society's Office

In an attempt to avoid the confusion which seems to exist even among our members, the Secretary once more calls attention to the location of the general administrative office which is situated at 2 East 103rd Street, New York City. The office at 100 State Street, Albany, houses the Legislative Bureau, and the office at 33 West 42nd Street, New York City, is that of Mr. Thomas R. Gardiner, Business Manager of the JOURNAL. Official communications sent to the Secre-

try should be addressed to the administrative offices

There have been no changes in the Secretary's general office staff of which staff he is justly proud. He feels that there exists nowhere a more efficient, courteous, and obliging group of employees. Without this staff and especially without Miss Baldwin, his office manager, the work could not be carried on as smoothly and efficiently as it is. Too much cannot be said regarding Miss Baldwin's wonderful knowledge of the workings of the Society, past and present, and her intelligent, comprehensive grasp of details.

Financial Department

In these times of financial stress, the Society is to be congratulated that its finances remain in the same capable hands which have guided and guarded them in the past. The Board of Trustees remains unchanged and it is to be hoped that it shall so remain for time to come. When Dr Chas Gordon Heyd gave up the Treasurership to assume higher duties there was some doubt as to the future of the office but Dr Frederic E. Sondern soon dispelled these doubts. When he in turn assumed higher rank these fears returned but as Dr Charles H. Goodrich, our present Treasurer, began his duties doubt was again dispelled and the Department is on as fine and solid a basis as it ever was.

Owing to various comments and inquiries regarding the appropriations, the Secretary again takes opportunity to inform the members that these appropriations are never paid in bulk but are more in the form of a drawing account, individual bills being rendered and when paid charged against the appropriation. Should the entire appropriation not be used the balance remains in the Treasury.

Legal Department

This Department remains under the skillful guidance of Mr L. J. Brosnan, our Counsel, and Mr T. H. Clearwater, our attorney. With Mr Brosnan's defense of malpractice suits our members are well acquainted but few know of the extremely valuable advice and assistance he has given the Executive Committee with which he sits at all its sessions.

The Secretary personally acknowledges with thanks Mr Brosnan's assistance and advice and his never failing courtesy.

Legislation

Through the mixes of political and legislative mysterious workings your Legislative Committee and Executive Officer have guided the Society without mishap. No legislation detrimental or prejudicial to the interests of the profession has been enacted and to date many bills supported by the Society have passed.

In the general rejoicing that the new compensation law has been enacted we must soberly consider what this means to the County Societies. Upon them will devolve onerous duties and great responsibilities and in accordance with the manner in which these duties are performed and the responsibility recognized will rest the success or failure of the measure. County Society secretaries should make an intensive study of this law, take due notice of its provisions, and act accordingly.

Committees

It is superfluous to say that the work of the Committees has been excellent—it always is. The loyal and self-sacrificing members of the Society who give their time and thought to these Committees deserve the thanks and commendation of the Society.

Your Secretary thanks the Chairmen of the Committees for their kind invitations to meet with them. Although he is constitutionally an ex-officio member of these committees he has always deemed it well to refrain from attending their meetings, as he believes the presence of an officer of the Society might hamper free discussion and the work of the committees. When he expresses his appreciation of the work he feels that he is voicing the opinion of the Society.

District Meetings and Conferences

It was with extreme regret that the Secretary found that his custom of attending the District Branch Meetings had to be abandoned. Time, health and weather were elements over which he had no control and he was able to attend but one meeting. He expresses his sincere

thanks to the Councillors for their kind invitations.

Some years ago he relegated to the Executive Officer, Dr. Lawrence, his duty of assisting in the organization and programs of these meetings and obtained from the Trustees a small annual appropriation to defray the expenses incurred by meetings of a "District Executive Committee." This plan has resulted in an increase of interest and growth in attendance and the meetings have been productive of much good to the Society.

This may also be said of the Conference of Secretaries and of Legislative Chairmen and the Secretary hopes that these Conferences be continued as being well worth the money expended.

The Secretary takes the liberty of calling the attention of the Councillors, especially those who assume office directly after the Annual Meeting, to their duties regarding visiting their County societies annually and investigating the condition of the profession in the County in accordance with Chapter 7, Section 10, of the By-laws. He stands ready to advise and aid them in this work (By-laws Chapter 6, Section 6).

General

The Secretary announces with great sorrow the death of our distinguished friend and associate, Dr. Wendell C. Phillips, former President of the Society and of the American Medical Association. On behalf of the Society the Secretary caused announcements to be published in the press and floral tributes sent. He recommends that the House by formal action pay fitting tribute to his memory.

Mention should be made of two activities which are still in their infancy and in the experimental stage: the District Committees, to contact organized groups within our ranks, and the Public Relations Bureau, under the auspices of the Committee on Trends. This Bureau is under the direction of Mr. Dwight Anderson with offices at 2 East 103rd Street, New York City.

To the President, Dr. Arthur J. Bedell, and to the other members of the Executive Committee, the Secretary extends his thanks for their support and friendship. He could not close this report without special mention of two men, Dr. Peter Irving, the Assistant Secretary, and Dr. Joseph S. Lawrence, the Executive Officer. When he says that these gentlemen are earnest, enthusiastic, and efficient workers and men of high character, he speaks advisedly, for he has worked, travelled, and lived with them. Their work deserves the commendation, not only of the Secretary, but also of the Society.

MEMBERSHIP STATISTICS

Membership December 31, 1933	12,578	
New members, 1934.....	736	
Reinstated members, 1934....	323	
		13,637
Deaths	157	
Resignations	97	
Membership automatically ceased through rescinded license	1	255
		13,382
Dropped for nonpayment of dues December 31, 1934.....		559
		12,823
Elected after October 1, 1934, and dues credited to 1935.....		349
		13,172

It is a pleasure to be able to report that there is a decided decrease in the number dropped for nonpayment of dues over last year. The list of Honor Counties is as follows: Broome, Clinton, Columbia, Delaware, Essex, Franklin, Fulton, Genesee, Herkimer, Montgomery, Ontario, Orange, Orleans, Oswego, Rockland, St. Lawrence, Schenectady, Schoharie, Schuyler, Seneca, Sullivan, Tioga, Tompkins, Washington, and Chenango—an increase of five Counties.

Respectfully submitted,

DANIEL S. DOUGHERTY, *Secretary*

April 1, 1935

REPORT OF COUNCIL

To the House of Delegates, Gentlemen

The Council has the honor of presenting the Annual Report which includes those of the Executive Committee, Committee on Publication, Committee on Insurance, and JOURNAL Management Committee

Two regular meetings have been held May 15, 1934, in Utica, and December 13, 1934, in New York City

Pursuant to the provisions of the By-Laws governing the constitution of the Executive Committee, the following members of the Council nominated by the President, were elected to serve with the Officers as the Executive Committee for the ensuing year Samuel J Kopetzky, C Knight Deyo, Clark G Rossman, John E Wattenberg, and Frederic C Conway

On nomination by the President, Frederic C Conway was elected Chairman of the Committee on Arrangements

It was decided that the 1935 Annual Meeting be held in Albany

On nomination by the President the following were elected members of the Standing Committees

Public Health and Medical Education
Russell L Cecil Leo F Schiff, Oliver W H Mitchell Martin B Tinker, Edward G Whipple and Clayton W Greene The Chairman of the Committee was granted the privilege of nominating the remaining members later

Public Relations William H Ross William D Johnson Augustus J Hambrook George M Fisher, and Thomas H Cunningham The Chairman of the Committee was granted the privilege of nominating the remaining members later

Economics Joseph P Garen Frederick M Miller, Joseph C O Gorman Cassius H Watson Terry M Townsend, Frederick S Wetherell, Edward T Wentworth, George C Vogt and Alfred E Shupley

Arrangements Stanley C Alderson Louis J DeRusso William P Howard, Joseph O Kiernan Richard A Lawrence Walter A Reynolds James F Rooney, and Edgar A Vander Veer

Legislation Bernard B Berkowitz, B Wallace Hamilton James F Rooney, and Leo F Simpson

The Executive Officer was officially designated to interview the Governor of the State of New York and bring to his attention the importance of having ade-

quate representation of the medical profession on his Special Advisory Committee on Relief and Welfare

A petition, requesting the creation of a Section on Physical Therapy, was referred to the House of Delegates

William A Groat was unanimously elected Chairman of the Committee on Scientific Work

The Council approved of the appointment of a Committee in each District Branch to contact those organized groups which exist within the ranks of organized medicine for the purpose of rendering available to the Officers and members of the Medical Society of the State of New York the objectives, studies, and purposes of these groups

The following resolution was adopted

In view of the determined and persistent efforts of certain foundations, welfare organizations, governmental agencies, and various groups of theorists with ideas based purely on sociological study to regulate and govern the practice of medicine, the Council of the Medical Society of the State of New York deems it both wise and necessary to reaffirm the stand against Compulsory Health Insurance and the regimentation of the Medical Profession taken on previous occasions and to place the Society squarely behind the ten points presented to and adopted by the 1934 House of Delegates of the American Medical Association And furthermore calls upon the Officers Committees and all loyal members to oppose and combat these evils wherever and whenever occasion arises with the distinct purpose of making known to the public and to the profession at large the official opinion of organized medicine in matters of importance to both physician and patient

A resolution seeking to interpret a previous ruling as to procedure of committee members when addressing other organizations was referred to the House of Delegates the Council, however, recording its opinion that the resolution in question should not be understood as estopping investigations, contacts, conferences with other organizations or with their representatives, which fall within the proper province of Committees

The following amendment to the Public Health Laws was approved

Providing that when the Public Health Council promulgates amendments to the

Sanitary Code, they shall not become effective until six months after they have been made, and that two members of the Public Health Council shall be practicing physicians.

Executive Committee

The Executive Committee has held regular meetings on the second Thursday of each month with the exception of July and August. At the first meeting it organized under the Chairmanship of Arthur J. Bedell. Samuel J. Kopetzky was elected Vice-Chairman. Lorenz J. Brosnan was appointed Counsel, and Thomas H. Clearwater, Attorney.

Although the work of the Executive Committee is of necessity more or less routine, it is of extreme importance. Many problems of interest to the welfare of the Society and of the Profession are constantly presented to it for solution and all of these have received most careful consideration.

In accordance with the By-Laws the Annual Budget was prepared and referred to the Trustees for the necessary appropriation.

The renewal of the contract with the Executive Officer was approved and referred to the Trustees.

James K. Quigley and Fairfax Hall were elected to fill the vacancies on the Committee on Public Health and Medical Education.

Wendell C. Phillips was elected to fill the vacancy on the Committee on Public Relations. Owing to the death of Dr. Phillips, James M. Flynn was appointed in his stead.

William A. Krieger was elected a member of the Committee on Scientific Work.

The following Special Committees were appointed by the President:

Medical Research: John J. Morton, Jr., Chairman, John Wyckoff, G. Canby Robinson, Augustus B. Wadsworth, Edwin MacD. Stanton, Herman G. Weiskotten, Joshua E. Sweet, Allen O. Whipple, Marshall Clinton, Winfield W. Scott, Burton T. Simpson, Frank A. Hartman, Simon Flexner, and Peyton Rous.

Prize Essays: Eugene H. Pool, Chairman, Walter W. Palmer, and Albert C. Snell.

Trends in Medical Practice: James F. Rooney, Chairman, Chas. Gordon Heyd, George A. Leitner, Floyd S. Winslow and

David J. Kaliski. Dr. Heyd having resigned, Nathan B. Van Etten was appointed in his stead.

Insurance: Charles H. Goodrich, Chairman, and Samuel J. Kopetzky.

Budget: Samuel J. Kopetzky, Chairman, Daniel S. Dougherty, and Charles H. Goodrich.

Publication: Daniel S. Dougherty, Chairman, Clark G. Rossman, and C. Knight Deyo.

JOURNAL Management: Frederic E. Sondern, Chairman, Peter Irving, George W. Kosmak, Samuel J. Kopetzky, and Thomas M. Brennan. Dr. Sondern having resigned, Frederic C. Conway was appointed Chairman in his stead.

To Revise the Constitution and By-Laws: Daniel S. Dougherty, Chairman, Samuel J. Kopetzky, and Frederic E. Sondern.

To Review Legislative Work: Charles H. Goodrich, Chairman, and Frederic C. Conway.

In accordance with Section 1265 of the Medical Practice Act, Orrin S. Wightman, Chas. Gordon Heyd, and Peter Irving were nominated to fill the vacancy on the Grievance Committee which occurred on December 31, 1934, through the expiration of the term of Dr. Wightman.

In accordance with the provision of Article 52, Section 1383, of the Education Law, Nathan B. Van Etten and Peter Irving were nominated to fill the vacancy on the Nurse Advisory Council which occurred on December 31, 1934, through the expiration of the term of Dr. Van Etten.

A letter was received from Dr. Rypins, Secretary, State Board of Medical Examiners, stating that the suit against the Life Extension Institute was in the hands of the Attorney General and the Assistant Attorney General, Sol Ullman, had applied to Mr. Justice Collins of the Supreme Court of the County of New York for leave to have the matter heard by the Supreme Court.

The resignation of William A. Groat as President of the Fifth District Branch was accepted.

The recommendation of the Special Committee to Review the Legislative Work, that either the Chairman or two members of the Committee on Legislation be residents of Albany was referred to the House of Delegates.

The definition of the Insurance Com-

mittee, that members in good standing are those whose dues were received prior to June 1, was approved.

The ruling which required that original articles must be read before an official meeting of the Society, Annual, District Branch, or County before being published in the JOURNAL was rescinded.

The recommendations that an Assistant to the Executive Officer and a full-time Field Officer be appointed were laid on the table.

It was voted to hold the next Annual Meeting on May 13, 14, and 15, 1935.

The creation of a State Bureau of Arbitration for Workmen's Compensation was disapproved with the proviso that if two or more adjoining Counties had a common urban center the establishment of a Joint Arbitration Board might be of value.

A Press Relations Bureau under the control of the Committee on Trends was organized for the purpose of securing the publication of the true position of the medical profession in the press of this and other States and further to point out, by all means possible, the danger of socialized and other forms of medical practice which are neither in the public interest nor acceptable to the medical profession, and to obtain such other publicity as may be for the good of the public and the profession.

The Aetna Insurance Company was granted permission to issue a binder for malpractice insurance to applicants for membership with the proviso that the policy may be cancelled if election be not accomplished within six months; the binder being revocable, retroactive to date of issue in case the applicant fails of election to the County Society.

The Physicians' Home was informed that it would be impossible for the State Society to assume control of the Home, as such action would be unconstitutional.

The Committee on Economics was instructed to discontinue the Study of Cost Analysis until the House of Delegates has had an opportunity to reconsider the action taken at the last Annual Meeting of the Society.

The President was empowered to communicate with the President of the Women's Auxiliary of the American Medical Association toward the forma-

tion of County Auxiliaries in New York State.

Committee on Publication

The main duty of the Committee on Publication is the supervision of the publication of the Medical Directory. In doing this every effort has been made to present the best book possible for the use of the members who have so valiantly stood by the State Society in these times of stress. In order to do this no detail has been omitted which will add to the value of the Directory, including the verification of all hospital appointments.

The cost, in spite of the increase in the edition of some 300 copies due to the growing membership, after the allocation of \$1.00 per member, is only \$200.00 more than last year, which under present conditions and the difficulty of obtaining advertisements seems to bode well for the future. In fact, the sales have already substantially increased since the first of the year.

Committee on Insurance

This Committee has considered various questions referred to them by the Executive Committee which decisions have already been announced to the Society membership.

The binder for malpractice insurance operative from date of application for membership is a new provision allowed by the Insurance Company.

To contribute to the prevention of malpractice suits, editorials have been inspired and written and published in the JOURNAL.

The percentage of members now insured under the Group Plan is 56 per cent. This shows no change from a year ago. The Committee urges that every effort be made to largely increase the percentage of members insured. There is no measure of security for the practicing physician more dependable than this insurance, and there is in these times ever increasing necessity for such security. Moreover, every new participant aids in the co-operative effort that is made by the Society to provide security for its members. Greater participation may result in lowering rates. It is therefore truly a fraternal enterprise and indicates 100 per cent as the desirable participation.

The Journal

When, on January 1, 1934, the Executive Committee set in motion new machinery for publication of the JOURNAL it had two primary objectives in mind; and both have been reached. The cost of production has been cut in half; and the reader-interest has been increased. It is confidently expected that these gains will be consolidated and that further desirable advances will follow.

In 1933 the actual annual cost was \$1.49 per member. In 1934 the figure was 69 cents. Comparison with the record of 1932 and 1931 is even more favorable. When it is recalled that the Executive Committee on instituting the new plan for publication advised that \$1.00 per member be allocated to meet all expenses, it should be particularly gratifying to the membership to learn of the low figure actually established.

That more interest on the part of readers has been displayed and that it is steadily rising, while not demonstrable in figures, appears to be proven by reports from all quarters of the State. Moreover, there has in recent months been a noticeable increase of the flow into the JOURNAL office of articles submitted for possible publication from authors through the State.

Looking to the future the Executive Committee sees no reason why the NEW YORK STATE JOURNAL OF MEDICINE, from this time forward, should not steadily command more and more atten-

tion both within the Society and from the profession outside the State. The Committee will not be satisfied until it is assured that the members by and large eagerly await each issue in the expectation of finding what each desires in scientific content, editorial comment, news of society activities, medicolegal information, book reviews, and finally, news of all sorts, not necessarily purely medical, but from the many human sources that touch the physician in his life.

A "general" medical journal, as distinguished from a special journal, should seek to supply high grade professional articles to all groups, general practitioners, specialists in all branches and teachers of medicine. It is intended that this pathway shall be followed in such fashion as to supply material desired by physicians even outside our own membership. Papers actually read before the Annual Meeting, before a District Branch, or before meetings of the 60 County Societies will, as in the past, receive prior consideration, but articles from other sources will be welcomed and judged according to their merits.

The JOURNAL Management Committee supervising publication under the Executive Committee deserves commendation for its actual achievements and for its vision of improvements yet to come.

Respectfully submitted,

DANIEL S. DOUGHERTY, *Secretary*

April 1, 1935

REPORT OF COMMITTEE ON SCIENTIFIC WORK

To the House of Delegates; Gentlemen:

Your Committee has held two general meetings and there have been several special conferences. The Chairman wishes to express his appreciation of the earnest co-operation received from the Chairmen and Secretaries of the various sections in the preparation of the Scientific Program for the Albany meeting. Following the custom of the more recent years, there will be scientific meetings for each of the sections on Tuesday morning, May 14, beginning at 10:00 and on Wednesday, May 15, at 9:00 A.M. with general sessions on Tuesday and Wednesday afternoons at 2:00.

We are especially indebted to the President of the Society, Dr. Bedell, for his personal efforts in arranging pro-

grams for the General Sessions. By his invitation we shall have the privilege of hearing on Tuesday afternoon both the President of the American Medical Association, Dr. Walter L. Bierring, and the General Manager and Secretary, Dr. Olin West, who will speak to us of the special activities of the Medical Association and its reaction to the present day social unrest. For Wednesday afternoon he has arranged a series of short practical talks on simple clinical topics by eminent men.

In the Medical Section for Tuesday morning, papers are entirely for clinical application and of varied interest, with a guest speaker who presents his researches on certain phases of the treatment of anemias. With Dr. William P. Murphy,

one of the Nobel Prize winners in medicine, presenting some of the facts concerning the treatment of the anemias as one of the speakers at the general session on Wednesday afternoon, the meeting as a whole will be noteworthy and authoritative in matters pertaining to the blood

On Wednesday morning in the Medical Section there will be a broad discussion of the value of induced pneumothorax in the treatment of the lobar pneumonias, first by one who has had a considerable experience in this very recent mode of treatment and followed by a group of internists who also have found interest in it and have had recent experience with it

In the Surgical Section there is for Wednesday morning a symposium on surgery of the chest quite worthy of special comment

Several new surgical procedures are discussed in the Section on Obstetrics and Gynecology, and some constructive ideas on the relation of the glands of internal secretion to growth and development are to be presented and well illustrated

In the Section on Neurology and Psychiatry, the Chairman gives his address on Wednesday morning, presenting his ideas on the place neuropsychiatry should have in a general hospital, and the program bears out the importance of this general hospital relation, since it includes papers on the value of the erythrocyte sedimentation rate, certain facts about intracranial hemorrhage, acute encephalomyelitis, and intracranial complications of purpura hemorrhagica

In the Pediatric Section it is notable that investigations of natural and artificial immunizing agencies against whooping cough have been undertaken and that the controlling effect of the hormones of the anterior pituitary upon growth in children is to be discussed

In the Dermatological Section the program while of undoubted interest to the dermatologist and syphilologist, also carries such practical topics as "Sensitivity to Soap Solutions," "Burning Tongue," "Nails and Their Diseases," and the "Treatment of Cardiovascular syphilis"—all of undoubted general interest

Evidently the Section on Ophthalmology and Otolaryngology found their experiment with the instructional hour preceding both the Tuesday and Wednesday morning sessions last year satisfactory for they are continuing the practice. Other sections might well consider it. On Tuesday there will be an hour's study of the pathology of sympathetic ophthalmia, and of the anatomy of the temporal bone and nasal sinuses on Wednesday

The Section on Public Health devotes one session to immunization and prophylaxis including a symposium on poliomyelitis arranged by Dr William H. Park in which he has the co-operation of his associates, Dr Neal, who discusses the treatment of acute poliomyelitis, and Dr Brodie, the active immunization against this fearsome disease of childhood. This should attract worldwide interest. Active immunization against poliomyelitis is so new that the early clinical statistics are still in process of collection and the presentation by Dr Brodie will be concerning their experiences to date

For the Section on Urology, Dr Laurie has arranged a program of fine scope and has for guests Dr George G. Smith of Boston, Mass., and Dr Alexander Randall of Philadelphia, Pa.

The program on Radiology shows in particular what mass statistics on such topics as cancer, gastrointestinal diseases, and tuberculosis can be collected and reviewed by men in this specialty, and, when they add as these essayists do, a correlation of clinical diagnosis and autopsy in groups of four and five hundreds of cases, one finds general applications that give pause

A very fine Scientific Exhibit has been assembled by Dr William A. Krieger, who has been in charge of this portion of the Committee's duties. All available space has been utilized and an increased number of exhibits of the very highest character accepted. Dr Krieger has found it necessary to decline a number of very fine exhibits for no other reason than lack of facilities, notwithstanding a generous increase in floor area over previous years. To a high degree the exhibits relate to papers presented in the various Sections and Sessions

It also has been the experience of the

Section Chairmen that far more papers of excellent character are available than could possibly be crowded into a two-day meeting. Your Chairman confidently predicts that we will soon be having a three- or four-day scientific meeting and an

exhibit hall filled with exhibits and demonstrations of medical progress and clinical investigation.

Respectfully submitted,

WILLIAM A. GROAT, *Chairman*

April 1, 1935

REPORT OF COMMITTEE ON LEGISLATION

To the House of Delegates; Gentlemen:

This Committee regularly reports its activities so completely through our bulletin service, and so many of you receive those bulletins, that it is difficult to write a report for this occasion that will be interesting. In recent years it has become customary for us to preface our report by saying that it has been an exceptionally busy year and a greater number of bills affecting the profession was introduced than the year before. To be accurate we make the same observation again. Last year, although our report was written a week later, we reported that of 3,600 bills before the Legislature, 180 were of sufficient interest to the profession to be followed by the Committee. This year over 4,200 bills have already been introduced, of which 215 are of interest to us.

Naturally, most of the interesting bills relate to compensation or welfare. The undesirable bills that have for so many years annually presented themselves in Albany; viz., the antivivisection, antivaccination, chiropractic, and osteopathy bills, are represented this year by one antivivisection bill which was killed in the Assembly Codes Committee. Among the compensation and welfare bills there is only one proposing a form of health insurance or socialization of medicine. At this time that bill is still in committee in both houses. The compensation bill of last year was rewritten along the line suggested by the Governor in his message, and passed both houses with enormous majorities.

The Committee had drafted, in accordance with your instructions of last year, a certain number of bills; viz., a clinical laboratory bill including x-ray laboratories, a modification of the Public Health Council personnel, and a hospital lien bill. All of these have been introduced. We also endeavored to have reintroduced the following bills: Nurse anesthetist, hospital dispensary, and

central registration bureau, but we found the legislators unwilling to sponsor them.

The Committee has met regularly in Albany for the purpose of studying the bills as they were introduced and instructing our Executive Officer as to the position he should take upon them with the legislators. The annual conference of County Society legislative chairmen was held in Albany on January 31. Thirty-three County Societies were represented.

We have increased our bulletin mailing list so that all the members of each County committee, where the chairman has sent us the names, have received the bulletins. This has increased the work very considerably in the Legislative Bureau, but we believe that it has been worth the extra effort and expense. A number of chairmen have so advised us and Dr. Lawrence has found that it has increased the correspondence with legislators. To date we have mailed eleven regular and eight special bulletins, and we have sent ninety-eight bills to the County chairmen.

A brief résumé of the most important bills that were introduced follows:

The State Fund monopolistic bill was opposed by us. The opposition was so great that, although it was one of the Governor's recommendations, it was abandoned and later a bill was passed providing for the future guaranty of insurance funds.

The occupational disease bill, which we opposed for a number of years, was reintroduced but it also gave way to powerful opposition and was amended so as to consider as occupational diseases only those already mentioned in the law. In this form we approved it.

An amendment to the Decedent Estate Law, which has passed both houses, provides that expenses of medical aid shall be deemed a proper element of damage recoverable in actions for wrongful act or neglect.

Extension of the Temporary Emergency Relief Administration for another year has been authorized

A distribution of a portion of the bills introduced according to the laws to be amended might be interesting. Twenty-five bills to amend the Education Law, fifteen to amend the Workmen's Compensation Law, seventeen to amend the Public Welfare Law, fifteen to amend the Health Law, five to amend the Labor Law

This is the first year in which the strands of the Legislative Committee on pending legislation has had active militant editorial support, through the alert-

ness of the JOURNAL Management Committee. This Committee desires to register its appreciation, and to recommend that the practice inaugurated this year shall be continued.

We again want to express our grateful appreciation of the hearty co-operation we have received from a majority of the County clurmen and the officers of the State Society.

This report will be completed by a supplementary statement after the adjournment of the Legislature.

Respectfully submitted,

HARRY ARANOW, *Chairman*

April 1, 1935

REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

To the House of Delegates, Gentlemen

Your Committee on Public Health and Medical Education begs leave to submit the following report for the current year.

In the hope that a large number of the members of the Society will read this report and discuss with their delegates, the subjects which are presented, the report has been made as brief as possible. In a general way the report follows the form of the previous annual reports from this Committee. The relative position of the various subjects is no indication of their importance.

Graduate Education

The following table is a report of the graduate courses which either have been given or will be given by the State Society for County medical societies during the current year.

Cayuga County	Internal Medicine
Chemung County	Malignant Disease
Clinton County	Internal Medicine
*Cortland County	Internal Medicine
Franklin County	Internal Medicine
Herkimer County	Internal Medicine
Jefferson County	Internal Medicine
Madison County	Internal Medicine
*Monroe County	Internal Medicine
Montgomery County	Internal Medicine
*Onondaga County	Internal Medicine
*Orange County	Pediatrics
*Rockland County	Pediatrics
St. Lawrence County	Internal Medicine
Steuben County	Internal Medicine
*Sullivan County	Physical Therapy
Tioga County	Internal Medicine

*An asterisk before the County indicates that the course has been completed.

Two lectures in the Orange County course were given previous to July 1, 1934.

Plans for all the above courses have not been definitely completed, so that there may be some change in the above schedule, although it is expected that it will be completed as given. Chemung, Jefferson St. Lawrence, and Sullivan County Medical Societies continue their record of having had a course each year since this work has been started by the State Medical Society. With the exception of four Counties, all County medical societies having courses this year, had courses last year and most of these have had courses annually for several years.

Three new courses have been added to the Committee's curriculum. Two of these are courses in Internal Medicine, and one in Pediatrics. The Committee is indebted to Dr. John Wyckoff, Dean of New York University and Bellevue Hospital Medical College, Dr. William S. Ladd, Associate Dean of Cornell University Medical College, and Dr. Charles Hendee Smith of New York City for their co-operation in planning these new courses. All of these courses have been given this year, and have proven highly satisfactory. This has been indicated particularly by the requests to have these courses repeated in other countries.

The Committee has no particular comment to make regarding graduate education at this time. This subject has been extensively discussed in its previous re-

ports. What has been said before still applies. Graduate education is continually receiving greater attention from all State medical societies. The work which has been done in New York State, is well known with the result that our advice is being frequently sought by others who are initiating this work. During the past year such advice has been requested by the Illinois State Dental Society, which is apparently the first State organization in that profession to undertake this work. At the annual conference of Secretaries of Constituent State Medical Associations of the American Medical Association in Chicago in September, 1934, Dr. C. L. Cummer, president of the Ohio State Medical Association, in a paper entitled "Educational Possibilities of Scientific Programs in State and County Meetings," spoke in approval of the plan of our State Society. A very close association has existed between the committees directing this work in the Massachusetts State Medical Society, and our own State Society. Tables have been prepared covering the work of this Committee in graduate education for several years, and will be offered for publication in the JOURNAL very shortly.

Public Health

The Committee on Public Health and Medical Education has been very active during the past year in the consideration of public health matters. Its major attention has been directed towards Child Hygiene, Maternal Welfare, Pneumonia, Standing Orders for Public Health Nurses, Nursing Education, and the general subject of interesting the physician in an active participation in the field of preventive medicine. For the purpose of studying these subjects, sub-committees have been appointed as follows:

Child Hygiene: Dr. Fairfax Hall, Professional Bldg., New Rochelle, N. Y., Chairman; Dr. Leo F. Schiff, Plattsburg, and Dr. O. W. H. Mitchell, Syracuse.

Maternal Welfare: Dr. James K. Quigley, 26 S. Goodman St., Rochester, N. Y., Chairman; Dr. Martin B. Tinker, Ithaca.

Pneumonia: Dr. Russell L. Cecil, 33 E. 61st St., New York City, Chairman; Dr. Clayton W. Greene, Buffalo, and Dr. O. W. H. Mitchell, Syracuse.

Standing Orders for Public Health Nurses: Dr. Edward G. Whipple, 277 Alex-

ander St., Rochester, N. Y., Chairman; Dr. Fairfax Hall, New Rochelle, and Dr. James K. Quigley, Rochester.

Nursing Education: Dr. Clayton W. Greene, 135 Linwood Ave., Buffalo, N. Y., Chairman; Dr. Russell L. Cecil, New York City; Dr. Martin B. Tinker, Ithaca; Dr. O. W. H. Mitchell, Syracuse; and Dr. Peter Irving, New York City. (At the request of the Committee, the Executive Committee designated Dr. Irving to serve on this sub-committee.)

Preventive Medicine: Dr. O. W. H. Mitchell, 307 S. McBride St., Syracuse, N. Y., Chairman; Dr. Clayton W. Greene, Buffalo, and Dr. Edward G. Whipple, Rochester.

Each of these sub-committees has submitted a report which has been approved by the whole Committee, and is appended herewith as a part of this report. The following comment regarding their activities describes their purposes and plans:

1. *Child Hygiene.* In June, 1934, Commissioner Parran of the State Department of Health sent a letter to the governing bodies of the ten Counties of the State showing the highest infant mortality rate during the period from 1929 to 1933. A copy of this letter was sent to the secretaries of the medical societies of the same Counties, and similar copies were sent to officials of the State Medical Society. At the request of the President of the State Medical Society, Dr. Arthur J. Bedell, our Committee was directed to study this matter. The sub-committee on this subject has made an extensive study of the matter of infant mortality throughout the State, with special attention to the ten Counties particularly referred to. The Committee has placed the material gathered as a result of its study at the disposal of the ten County medical societies, and has offered its assistance in any effort which the County societies make to reduce infant mortality rates in their particular Counties. In its letter to the County medical societies, the sub-committee made the following statement: "Because of the many factors involved, such as social, economic and racial, it is not to be expected that the rates will be the same in all the Counties. These differences should be determined, and every effort made to ascertain the causes of deaths which could have been prevented." The title of this sub-committee has been changed to the sub-committee on Child Hygiene, and it proposes to make its facilities available to all County medical societies in a broader respect.

2. *Maternal Welfare.* The sub-committee

on Maternal Welfare is continuing the work which was outlined in our last annual report. Our Committee has been asked by the National Maternal Welfare Committee to represent it in New York State, and has agreed to so do. The Executive Committee has been requested to approve this action. The National Maternal Welfare Committee is a joint Committee representing the American Child Health Association, the American Association of Obstetricians and Gynecologists, and the American Gynecological Society. Its plans and purposes are similar to those undertaken by the maternal welfare committees of some of the State medical societies, notably that in New Jersey. It is anxious that it have as its representative in each State the proper committee of the State medical society. The work which the Committee on Public Health's sub-committee on Maternal Welfare is doing corresponds to the plans and purposes of the National Maternal Welfare Committee. Therefore, it would seem highly desirable that the Committee act as the representative in New York State for the National Maternal Welfare Committee. A letter has been sent to all County medical society officials of the State, requesting that they appoint committees to handle this problem in their own County societies. Replies so far received from twenty-five County societies indicate that Maternal Welfare Commissions have been active in four County societies. Twelve County societies have appointed such Commissions, following the receipt of the above mentioned letter. The other nine County societies have promised to give this matter their immediate attention.

3. *Pneumonia.* At a meeting of the Public Relations Committee on December 13, 1934, the matter of pneumonia mortality was discussed with representatives of the Metropolitan Life Insurance Company, who reported on the lack of nursing care in these cases. The Public Relations Committee appointed a sub-committee to study this matter, and asked that a similar sub-committee be appointed by the Committee on Public Health and Medical Education. It was soon apparent that this topic was wholly a public health matter, and the sub-committee from the Committee on Public Health and Medical Education was asked to assume entire charge of the subject. The sub-committee feels that its attention should be directed towards all phases of the pneumonia problem, and that an energetic campaign should be waged in this State for the control of the disease. It has already made progress in its co-operative efforts with Commissioner Parran, so that an additional appropriation has been

made to the State Department of Health, to provide for the distribution of the newer concentrated pneumonia serum. The Committee on Public Health and Medical Education feels that a campaign to control pneumonia should be directed by the State Medical Society through its Committee on Public Health and Medical Education. It may need the assistance of co-operative groups on an advisory committee, and requests permission from the House of Delegates for the appointment of such a group. An educational exhibit regarding pneumonia will be sponsored by the Committee at the State Society's annual meeting.

4. *Standing Orders for Public Health Nurses.* The need for Standing Orders for Public Health Nurses is apparent. Each County medical society should adopt its own set of orders. Many County medical societies have already done so. In order to aid such County societies as have not already done so, the sub-committee in its report has set forth such a code. It should be definitely understood that this code does not replace any already adopted by any County medical society.

5. *Nursing Education.* The question of changes in nursing education were reported upon in our last report, and the sub-committee to study this subject has made an extensive study with recommendations included in their report. Your attention is directed to the fact that while the State Department of Education had considered its plans for changes in nursing education with various groups, it had not considered these suggested changes with any representative group of the medical profession, until this Committee was asked to study this problem.

6. *Preventive Medicine.* The sub-committee to formulate a plan regarding preventive medicine has submitted no report. It has been felt that until some of the other activities of the Committee were further advanced, it would be unwise to do anything with this subject. Furthermore, work more or less along these lines has been started by several County medical societies, notably Albany, Nassau, and Westchester Counties. During the coming year, the experiences of these societies can be made available to other Counties, and efforts made to initiate in their Counties similar activities. The Committee has in mind a well-developed educational program, to be carried on through the JOURNAL, in the field of preventive medicine.

The Committee continues to take a general interest in the subjects of tuberculosis, cancer, venereal diseases, and

arthritis. It has no definite report to make regarding these subjects at this time. The joint sub-committee on the Deaf and Hard-of-Hearing, which represents the Public Relations Committee and this Committee, is continuing its study, and will make a separate report. This sub-committee is planning an exhibit at the annual meeting of the State Society, and permission has been requested that one of its members, Dr. Fairfax Hall, discuss the work of this sub-committee in the Section on Pediatrics.

Report of Sub-Committee on Child Hygiene

Your sub-committee on Child Hygiene in November wrote letters to the secretaries of the medical societies of the ten Counties of the State having the highest infant mortality, suggesting that these County societies take some action to improve health conditions amongst infants in their Counties. An analysis of the infant mortality of these Counties was enclosed together with an outline of procedure tending to lower infant mortality. It was stated that a representative from this Committee would, upon request, meet with them to discuss this matter. Dr. Schiff attended a meeting of the Franklin County Society for discussion of this subject. Dr. Mitchell attended a meeting of Chenango County. No replies have been received from these Counties regarding this matter.

The sub-committee has asked Dr. Parran of the State Department of Health to supply us with information on all matters pertaining to child hygiene. Dr. Parran replied that he would co-operate to the fullest extent and has asked Dr. Elizabeth M. Gardiner and Dr. J. V. DePorte to report all new developments concerning infants and young children. He stated that the Department had under consideration infant mortality surveys in St. Lawrence, Clinton, and Warren Counties to be taken up in co-operation with the County Societies. He said that if the Wagner Bill is passed there will be many questions of policy and procedure in regard to child health which he will wish to take up with this Committee.

There are several matters relating to child health which may be well considered by this sub-committee at this time for

recommendations as to action in the future.

FAIRFAX HALL, *Chairman*

Report of Sub-Committee on Maternal Welfare

The sub-committee on Maternal Welfare believes that Maternal Welfare Committees should be organized in County Societies throughout the State where none exist at present. The function of such committees shall be to make a study of the facilities for maternity care in each County including prenatal and natal care, to study the maternal mortality in each County, and after such studies to attempt to improve local conditions by education of the public and by placing the seriousness of the situation before the medical profession in the effort to secure their co-operation to better conditions.

This move seems necessary in view of the last annual report on maternal mortality from the State Department of Health which showed that while the mortality rate for the State as a whole was no worse than the national rate, nevertheless it might be improved and in addition it showed an unusually high death rate for the maternal state in some Counties.

Committees on Maternal Welfare are operating in some County societies and it is hoped that the results will equal those in New Jersey where such work has been carried on for several years. In addition the State Society has been asked by the National Committee on Maternal Welfare, a very representative group, to co-operate in this work and appoint a representative to serve on the National Committee.

JAMES K. QUIGLEY, *Chairman*

Report of Sub-Committee on Pneumonia

As chairman of your sub-committee on Pneumonia, I beg to make the following report:

At the first meeting of this committee, we decided to focus our efforts on two immediate goals.

First, to put on a scientific exhibit at the New York State Medical Society meeting in Albany this Spring. In this exhibit we propose to show by charts, movies, and laboratory demonstrations,

the recent advances in the diagnosis and treatment of pneumonia, stressing particularly bacteriology and serum treatment. Dr. Parran has very kindly consented to have the laboratory work done by the New York Public Health Laboratory in Albany.

Second. Our other immediate objective has been to arrange for an adequate supply of concentrated serum to be prepared by Dr. Wadsworth in the New York State Health Department's laboratory at Albany. Governor Lehman has recommended an additional appropriation of \$25,000 for the preparation and distribution of this serum.

In the Fall your sub-committee proposes to take up other phases of the question, such as a publicity campaign to doctors, nurses, and the public on the prevention and treatment of pneumonia, training of laboratory technicians in the modern methods of typing, and close co-operation with a similar pneumonia campaign which is to be conducted by Commissioner Rice in New York City in conjunction with the medical societies of the five boroughs of greater New York.

RUSSELL L. CECIL, *Chairman*

Report of Sub-Committee on Standing Orders for Public Health Nurses

The daily routine of public health nurses, visiting nurses and school nurses continually brings them in contact with individuals needing nursing care and advice. It is highly important that such care and advice be consistent with the consensus of medical opinion of the community, and for this reason, it is suggested that each County medical society adopt certain standing orders for the guidance of these nurses. The following are submitted by the Medical Society of the State of New York with the suggestion that they be approved by the various County medical societies, with such changes as may be in their opinion advisable as standing orders for the guidance of public health, school, and visiting nurses, which have not already adopted such a code of Standing Orders for this purpose. It is recommended that the Medical Society of the State of New York approve of these Standing Orders for the guidance of the work of such nurses in Counties which fail to set

up a code of their own or until they do so.

The services of the Public Health Nurse are considered under two headings: (1) Nursing Care, (2) Health Education. In general, it may be said that it would be a rare occasion when the Public Health Nurse gives nursing care without giving, verbally or by demonstration, education in the field of prevention of the condition which she meets. Administration of relief is not considered here. *All new patients should have pulse, temperature, and respiration recorded, and be given such bedside care as seems necessary.*

Most of the conditions met by the public health nurse where treatment may be given on the first visit, based upon standing orders from the physician, are given below.

Emergencies and Accidents; Nursing Care. This should be well covered by the first aid training of a Public Health Nurse, and executed accordingly. Only first aid should be given and immediate contact should be made with the attending or family physician or headquarters. In the event of a severe accident the nearest physician or hospital should be called, and the attending or family physician be notified of the disposal of the case. Subsequent nursing care should be carried out on the instructions of a physician or Public Health official.

Health Education. Little can be done on the first visit. Accident prevention can be emphasized later.

Elevated Temperature; Nursing Care. Put patient to bed. Give tepid sponge bath if patient is restless or markedly uncomfortable, liquid diet.

Health Education. None at this time.

Abdominal Pain (with or without diarrhea or constipation); *Nursing Care.* Put patient to bed, nothing by mouth, other than sips of water. No medicine, cathartics, or enema until ordered by physician. Make immediate contact with physician or local relief agencies, especially if fever is present.

Health Education. Emphasis of above.

Communicable Diseases; Nursing Care. If communicable disease is suspected, so inform family. Isolate the patient. If the family cannot afford the services of a physician the nurse should notify the Health Officer at once.

Health Education. Emphasis on the necessity of above. All sore throats should be considered as possible communicable diseases. The nurse should follow the

regulations of the Health Department as a guide to the advice she gives regarding isolation and quarantine. She should give instruction to the attendant regarding the care of patient and prevention of contacts.

Colds; Nursing Care. If fever is present put patient to bed and notify physician. If no fever, advise patient regarding the infectious nature of a cold and use usual methods for isolation and disposal of secretions as prescribed by local or state health authorities.

Health Education. Instruction regarding infectious nature and disposal of secretions and the importance of sequelae.

Tuberculosis; Nursing Care. Usual bedside care with special care to secretions and excretions.

Health Education. Patients suffering from tuberculosis should always be under the care of a physician, but they often report to him at long intervals. The nurse will be guided by the physician's advice regarding sanatorium care. Where there is no private physician, the clinic or health officer should be consulted. In the absence of special orders the nurse should give periodic supervision, giving advice regarding accepted standards of hygiene for tuberculosis patients, stressing rest, diet, fresh air, care of sputum, and protection for the contacts including regular physical examination particularly for children.

Pulmonary Hemorrhage; Nursing Care. Notify physician. Reassure patient. Demand complete rest, ice bag to chest. Await physician's orders for further treatment.

Health Education. None at this time.

Ear Ache or Discharging Ears; Nursing Care. None other than to seek medical supervision.

Health Education. Instruction regarding disposal of secretions and importance of medical care.

Inflammatory Condition of Eyes or Eyelids; Nursing Care. None other than to isolate and seek medical care at once.

Health Education. Instruct regarding possibility of dangerous consequences connected with inflammation of eyes or eyelids and of possibility of its infectiousness.

Surface Injuries or Infections; Nursing Care. Dressings for minor injuries or surface infections. Cleanse with soap and water and apply iodine if the injury is fresh. Cover injury or infection with a loose sterile dressing and seek medical attention.

Health Education. Instruct regarding the serious possibilities of any superficial or deep wound or infection.

Burns; Nursing Care. Remove clothing over burn if not attached to skin; if ad-

herent, cut clothing away. If burn is of first degree, apply sodium bicarbonate solution and exclude air by dressing, and seek medical advice. *Do not apply oil or any greasy substance.* If burn is of second or third degree, use only sterile dressing and seek immediate medical care.

Prenatal Visits; Nursing Care. Little is required other than routine nursing care. The importance of this visit is:

Health Education. All expectant mothers should be under medical supervision, and the importance of this should be emphasized by the nurse. Routine instruction in personal hygiene, including habits of living, importance of fresh air, sleep, rest, exercise, baths, dress, diet, and recreation are important. In follow up calls, it is advisable to take pulse and temperature readings and to have recorded routine urinalyses and blood pressure readings. Special advice regarding the care of the nipples should be given after the sixth month of pregnancy. Advice regarding layettes and other supplies may be given. A report of each prenatal visit should be sent to physician in charge of case, and any adverse symptoms should be reported to him immediately.

Maternity Care; Nursing Care. While awaiting the physician: (1) Arrange bed for right hand delivery; (2) arrange room and patient's supplies; (3) see that there is a supply of hot and cold sterile water; (4) if labor has not progressed too far give low soap enema (1 pint); (5) clip or shave pubic hair; (6) cleanse external genitals with soap and water.

If baby is born before the doctor arrives, the nurse should, pending the arrival of the physician: (1) Clamp and cut the cord, making sure that enough is left for the physician to tie; (2) see that respiration is well established; (3) Keep baby well wrapped and warm; (4) cleanse the eyes with boric acid and put one per cent silver nitrate solution in each eye; (5) hold the fundus of the uterus for 30 minutes; (6) in case the placenta is not expelled and hemorrhage occurs express the placenta by the Credé method. Keep mother warm and quiet until physician arrives to assume responsibility for mother and baby.

Post Partum and New Born Care. If the physician is in attendance get orders from him. If no physician in attendance proceed as follows:

Nursing Care; Post Partum Hemorrhage. In the event of post partum hemorrhage: (1) Attempt to hold the fundus of uterus firmly between the fingers; (2) send immediately for family physician, and if unable to reach him call nearest physician;

(3) elevate foot of bed; (4) apply ice pack to abdomen.

Usual Post Partum Care. Record temperature, pulse, and respiration, give cleansing bath, give perineal irrigation of sterile normal salt with boiled water or boric acid solution, cleanse nipples before and after nursing with boiled water or boric acid solution. Apply sterile mineral oil to nipples and cover with sterile oil paper. If breasts are engorged, apply supporting binder. Usual attention to bowels and bladder. Get special instruction for sore or cracked nipples.

New Born Care. Record temperature, pulse and respiration, give cleansing bath, change outer cord dressing if soiled, cleanse genitals with mineral oil and oil all creases in body, record weight, prepare separate bed for baby so that proper temperature may be maintained. If premature, or under five pounds in weight, or in poor condition, do not give usual bath, but cleanse with warm oil. Keep baby warm and avoid unnecessary handling.

Inflamed Eyes. Notify physician or responsible authority at once.

Bleeding from Cord. Tie tightly and securely with sterile tape, apply sterile dressing and tight binder. Watch for further bleeding, notify physician.

Protruding Umbilicus. If umbilicus is clean and dry, make deep vertical fold of skin and apply tight adhesive $1\frac{1}{2}$ inches wide.

Diarrhea. Urge complete rest, discontinue all feeding, give plain boiled water, notify physician.

Excoriated Buttocks. Cleanse with oil, instruct mother regarding care of child and diaper.

Convulsions. Send for physician at once, undress child, and move as little as possible, give warm (105° F.) mustard bath (1 teaspoonful of mustard dissolved in a little tepid water to 1 gallon of warm water). If no tub is available, give hot pack. Keep cold compress to head, following bath or pack, place patient between warm blankets, and maintain absolute rest.

Health Education. Instructions regarding above naturally follow the nursing care.

School Nursing. It is only outside of metropolitan areas that the Public Health Nurse does school nursing. It may be necessary for the nurse to render first aid, but it would seem advisable to give no other nursing care or health education except on advice of school physician, family physician, or health officer. This will avoid the assumption of the responsibility of diagnosis placed upon the nurse when she treats any abnormal physical condition. The nurse

should report to the school physician any abnormality found and in the event that she observes a communicable disease, the nurse should recommend dismissal from school and that the family be notified, she should notify the family physician or the school physician of her observations and recommendations.

Child Welfare. The duties of the Public Health Nurse in reference to child welfare are entirely supervisory and educational. A general outline follows: In health supervisory visits to young infants, emphasis should be placed on breast feeding, unless the physician has left other instructions. Instructions according to accepted standards of infant care should be given regarding: (1) Establishment of regular habits of sleeping, eating, and elimination, aids to forming other desirable habits should be discussed as the need arises; (2) daily care, such as cleansing baths and sun baths, type and care of clothing; (3) fundamentals of nutrition and the need of starting such foods as orange or tomato juice and cod-liver oil in the early months of life; (4) need of taking to physician for immunization against smallpox when one year old and diphtheria when 6 months old; (5) when physical defects are present and recommendations for correction are outlined by the physician, the nurse should encourage and secure aid if necessary to carry out the physician's orders.

General. It may be said that in the course of the work a nurse will be expected to take advantage of every opportunity to give instruction regarding the procedures for the care of the sick, the prevention of disease with emphasis on the rules for the maintenance of health. Where she finds evidence of existing defects or of illness, she should use her influence to secure speedy medical or dental care. She should always be most careful neither to diagnose nor to recommend treatment of any kind; nor should she ever suggest a particular physician, even though the patient has no regular one and asks her advice.

EDWARD G. WHIPPLE, *Chairman*

Report of Sub-Committee on Nursing Education

Your committee was asked to study the "Suggested Remedial Measures" recently proposed by the New York State Education Department designed to improve the nursing situation within the State. Members of the committee attended several conferences, including one of all the nurses of the metropolitan district called to discuss these same measures, and the

annual meeting of the New York State Nurses Association. A conference was held with Dr. Horner, Assistant Commissioner for Higher Education, who is the author of the suggested remedies.

It is apparent to all that a situation has arisen in the nursing profession which works hardship for the nurses and the community. There has been an overproduction of "trained nurses" and a consequent undue increase in the registered nurses within the State. The training of many of these has not been of the best. The number of unlicensed nurses, many of them coming from other States, likewise has increased. With the deepening of the economic depression there is a great surplus of nurses above the demand and many of the nurses, both licensed and unlicensed, are in dire straits.

Undoubtedly in the past there have been too many training schools, and too many nurses have been graduated. The comprehensive report of the Committee on the Grading of Nursing Schools shows that since 1920 the number of trained nurses in the United States has risen rapidly while the number of untrained nurses has maintained a steady level. One of the remedies suggested is that a moratorium be declared on admission of students to training schools until September, 1936. The wisdom of this is doubtful. Many hospitals would be greatly handicapped should such a rule be enforced and such prohibition of opportunity would not be fair to the oncoming generation of young women. Whereas the training schools have saved money for some hospitals in furnishing care of the sick, such has been by no means universally the case. In the better hospitals, in recent years, at least, the training schools have been conducted at a financial loss. Various factors are operating to help the situation. Numerous smaller training schools are being closed voluntarily; the number of applicants for nurse training has fallen off sharply; and many hospitals have greatly increased the proportion of their work done by graduate nurses on general duty.

The proposal that a year of college work be required of all candidates for "R. N." is open to question. Over-training leads to fatal inefficiency in the essential qualities so necessary in the

nurse on duty. Nursing is as yet an art based on certain sciences and your committee feels that the best training is to be obtained in the presence of sickness.

The matter of the trained attendant and the practical nurse presents a problem. The needs of the patient may be widely varied. He may require only a purely household helper giving attention to an invalid or convalescent such as any maid could render, or he may need the most skilled and competent service a nurse can perform. To meet such needs, different degrees of training are required. The present provision in the law is inadequate, and revision is in order. It has been found well-nigh impossible to define the practical nurse.

Dr. Horner has done us all a service by calling attention to the plight of the graduate nurses and the present situation in nursing education. The New York State Education Department plans to continue its consideration of these matters and appears to desire the co-operation of this Society in formulating remedial measures. If it is your wish, your committee will continue its study of the entire question.

CLAYTON W. GREENE, *Chairman*

Recommendations

The Committee is anxious to have the House of Delegates express itself particularly on the following matters.

It is recommended that the sub-committee on Child Hygiene be continued and that this sub-committee study and investigate all phases of this subject, and that it continue its efforts to interest County medical societies in assuming leadership in the efforts to reduce infant mortality in their particular Counties, and to have the individual physician participate more actively in this work.

It is recommended that the Committee on Public Health and Medical Education be designated as the New York State representative of the National Maternal Welfare Committee, and that the sub-committee on Maternal Welfare continue its efforts to organize Maternal Welfare Commissions in every County medical society for the purpose of assuming leadership in this activity.

It is recommended that the House of Delegates approve of a campaign to re-

duce the mortality from pneumonia to be conducted by the State Medical Society through its Committee on Public Health and Medical Education and that this campaign consider all phases of the pneumonia problem, including medical treatment, distribution of serum, laboratory facilities, nursing care, and the education of the public. It is recommended that the direction of this work be wholly in control of the State Medical Society, through its Committee on Public Health and Medical Education, but that the co-operation of all interested groups be secured, and an advisory committee representing these groups be appointed by the Committee on Public Health and Medical Education.

It is recommended that the sub-committee on Nursing Education be asked to continue its general study of this question, without any power to take any action.

General Comment

The annual appropriation made to the Committee on Public Health and Medical Education has been reduced each year for the last successive three years. Despite this fact, the Committee is carrying on the same program of graduate education, and is doing more work in the field of public health. It has utilized every possible means of economy in carrying on its work. Much of the work of the Committee has been done by sub-committees in order to reduce expenses, and at the same time to increase efficiency. The Committee has held three general meetings. Most of the meetings of the Committee and its sub-committees have been held on Saturdays, in order to take advantage of the lower week-end railroad fares. The Committee has requested the assurance from the Executive Committee of slight additional funds if necessary to complete this year's program.

The activity of the Committee on Public Health and Medical Education has

an important bearing on the changes being suggested in medical practice by certain groups at the present time. The annual reports of this Committee show that the State Medical Society has interested itself in the continual education of the physician and the improvement of medical practice, long before these other groups had even considered these questions. At the present time, non-medical groups are very active in their efforts to expand governmental public health work. Your Committee has taken the view that future health programs must be concerned more and more with the individual practicing physician, and believes that capable governmental public health officials realize this, and are anxious to co-operate in the proper way with the medical profession in accomplishing this. The Committee on Public Health and Medical Education is prepared to offer its services along these lines to the County medical societies. The greatest weakness in such programs is the lack of well-organized committees in the local County societies, to take advantage of the services which this Committee can offer.

The Committee expresses its appreciation of the co-operation received from the President and the other officers of the State Society during the present year, as well as of the services rendered by the very many interested physicians throughout the State. Most harmonious relations have existed between the other Standing Committees and this Committee. The Chairman wishes to acknowledge the unselfish service of all the members of the Committee who have actively participated in its efforts, and who have attended all meetings of the Committee except in a few instances when unavoidably detained by illness or some other equally justifiable reason.

Respectfully submitted,

THOMAS P. FARMER *Chairman*

April 1, 1935

REPORT OF COMMITTEE ON ECONOMICS

To the House of Delegates, Gentlemen

Your Committee on Economics herewith submits a report of its activities and events of economic interests for the year. Of particular significance are

1 Survey of laws regulating public and

semi-public medical care "TERA"

2 Epstein Bill Compulsory Sickness Insurance "Will America Copy Germany's Mistakes?"—Hartz

3 Workmen's Compensation

4 Preliminary draft of "planned

changes for a program of medical care for New York State."

5. Conference with Hospital Association: continued.

6. Visit of Metropolitan Medical Economists to Philadelphia.

7. "Eastern Interstate Medical Economics Conference," first meeting.

8. Extended application of the Vaughan plan.

9. Meeting the expense of medical care through Financed Credit.

10. Rationalized insurance for sick-care expense.

11. "A New Deal" in Philanthropy.

12. Contacts with other groups.

13. Cost Analysis (Medical Practice).

14. Survey of positions for physicians in the public service; State, County, City.

15. Medicine in Industry. Practice of medicine by corporations: lay technicians.

16. Physicians in courts.

17. Promotion of economic thought by circulation of informative material.

18. News Bulletins: Committee minutes.

19. County Society and other public addresses.

20. The work of the Committee.

21. Acknowledgments.

Each item of this list represents days and weeks of work by the committeemen, who have served you. A reasonably detailed report would extend any one item beyond the space allotted for our full report. This abridged text is offered with full appreciation that much is left to the reader's general comprehension of the nature of the work. Supplemental material will be provided for consideration by the Reference Committee.

1. "Public and semi-public assistance for the provision of medical care in the State of New York" is regulated by fragments of law scattered through more than ten different statutes. These have been collected, briefed, and now are being circulated in a 125 page loose-leaf book: expression of opinions based on personal experience is being solicited from the field of actual application of their provisions. This study is related to comment in paragraph 4. This project should mature to a definite recommendation by September 1, 1935.

"Regulation 7" (obtainable from Tem-

porary Emergency Relief Administration, 79 Madison Avenue, N. Y. C.) is a book of general and administration data.

2. Shortly after the first copies of the Epstein Bill were released by the American Association for Social Security (the old American Association for Labor Legislation with a new name) we circulated 600 mimeo reproductions throughout the State.

Drs. Borzell and Faught directed our attention to the Hartz pamphlet—"Will America Copy Germany's Mistakes?" Through the generosity of the Pennsylvania Self Insurers' Association, we sent out 400 copies of it in January. Later, Mr. Walter Linn granted us permission for the publication, which appeared in the March 1, 1935, issue of the JOURNAL.

Epstein has become "Byrne Bill, Int. 474" in the New York State Senate. We urge every member to exercise every opportunity to educate his people to the truth about this bill.

It is obvious that the proponents are interested more in the even spread of "Jobs" and in the taxation of industry than they are in the *quality* of the medical care. A *leveled poor quality* of medical care will be a greater evil than the present unevenness of the burden of expense imposed by sickness. Compulsory Health (Sickness) Insurance "must not pass." If we must have "compulsion," let it be "compulsory saving"!

3. One provision of the proposed O'Brien "19" amendment to Workmen's Compensation Law calls for the composition of a fee schedule. We are prepared further to offer "guiding principles" if and when the County societies are required to register qualified physicians with the Commissioner of Labor. We have exchanged ideas with officials of insurance, for the purpose of finding a common ground of understanding upon which this law may be made to work more satisfactorily for all interests, workmen, employers, physicians, and "carriers." Without such foundation, no law can function smoothly.

(Since this report was written Governor Lehman signed the Amendment to the Workmen's Compensation Law—O'Brien 19. The essentials of this law amendment were originally drafted in the

report of this Committee and passed with amendment by the House of Delegates at the 1933 meeting.)

4. Certain interests and "minorities" are urging "change" in the social order. They have attempted the induction of artificial trends in substitution for the processes of natural development.

Why not meet the challenge of their ill-conceived "plans" for medical care with a program of fundamentals "for the maintenance of present standards and the further natural development and more universal application of health and medical service to all the citizens of New York?"

The Program: (a) Re-write and consolidate the laws to provide medical care with compensation of the professions, for all who cannot obtain it without public assistance; discontinue the further exploitation of the profession in the dole of free service. [1]

(b) Integrate the entire profession in the functions of "public health." [8]

(c) Establish "bureaus" for proper investigation and reasonable adjustments and diversification of expense of sick care to income and time-payment ability of those who need it. (Washington, D. C. plan.) (Pino plan.) [9]

(d) Educate those who need credit "to borrow money" on a deferred payment plan, and procure professional service on "cash" basis. Establish bank facilities for the humanities as well as for the industries of life! [9]

(e) Develop an "insurance" plan limited to meet the real financial hazards of high-cost or long-duration illnesses: and free from political implications and potentialities and the evil of lowered quality of medical care. [10]

(f) Compulsory savings for all low-wage earners. (Hartz) [2]

5. Conference of this Committee with representatives of the State Hospital Association has continued. In these informal conversational exchanges a mutual understanding has been promoted which already has led to considerable progress in the correction of certain wrongs affecting the economic welfare of medicine. It lies within the power of "hospital administration" to go far toward corrective adjustments of *methods* and *regulations* without recourse to amendment of any statute. There seems a ready willingness to meet all reasonable desires of the

profession. If the common welfare of both sides is to be attained, on the ground of harmony of economic interests, this will be found not in continued legislative conflicts, but must arise out of friendly, analytical group-thinking. Present indications foreshadow increasingly favorable results in control of "free" and "pay" clinic abuses.

6. On the evening of December 19, 1934, the Commission on Medical Economics of Philadelphia County Medical Society, at a dinner meeting, explained and demonstrated its plan of organization and activity. A Commission of 4 motivate the work of some 18 sub-sections. The plan spreads the interest, the work, and the effectiveness of the economic study to a very considerable number. Twenty physicians from 7 New York metropolitan Counties and 2 physicians from Hudson and Essex Counties, N. J., made the journey to the meeting. Kings County has adopted the organization plan and now has 120 of its members engaged in the medical economics' activities.

7. Thirty-eight physicians, including our Committee, informally representing the economic thought of the medical societies of 8 eastern States, met at Atlantic City on January 27, 1935. A day of general discussion ended in a resolution to: (a) Constitute a permanent association for further exchange of information and opinions in medical economics; and to (b) facilitate composition of united regional strategy and action: and thus amplify the purposes of competent authorities of respective States, and the American Medical Association.

The "Eastern Interstate Medical Economics Conference" lays the foundation for a better regional or "neighboring-state" co-operation, founded upon closer acquaintance and mutual good will. Address: Dr. F. F. Borzell, Secretary, 4940 Penn Street, Frankford, Philadelphia, Pa.

This Conference came about through the pre-existing cordial relations among Dr. Thomas Lewis, Chairman of the Committee on Medical Practice, New Jersey; Dr. Francis Faught, Chair. Commission on Medical Economics, Philadelphia County; Dr. F. F. Borzell, Chair. Economics Committee, Pennsylvania; and Dr. Fred Elliott of the New York State

Committee on Economics. Tangible benefits have accrued from this informal group unity.

8. The Vaughan plan of Public Health administration and organization to integrate all practicing physicians in the program, with compensation for them, and the substitution for Health Department Clinics of "Public Health Hours" in the offices of private physicians, has been approved by the State Society. Local County initiative must assume the responsibility of urging the extended adoption of this plan. Commissioner Rice of New York City is reported interested in a test of the plan in one area of the City, and only awaits available funds.

9. Credit and its function, applied to the provision of medical care, has developed more evils than good. This Committee sounded the opinion of more than a hundred representative County and State Society officers with prepared statements on "Meeting the Expense of Medical Care" and "Financed Credit."

At its December, 1934, meeting, the Council endorsed, for the Medical Society of the State of New York, "the principle of periodic payment of the expense of medical care out of income, through established, accredited agencies." This Committee at present, by instruction of the Council, is engaged in discussion with banking interests, toward the development of a plan to be submitted to the Executive Committee when completed. (See 4) [Cf. the JOURNAL, April 15, 1933, "Financing Sickness."]

Dr. Pino in Detroit and Ross Garrett in Washington, D. C., direct successful bureau-service to public and professions, largely with employer's co-operation.

"Credit and debt" should not be permitted to build an impassable barrier between physician and patient.

10. The Thomas Thompson Fund, Brattleboro, Vt., has demonstrated that insurance—which leaves procurement of service to the choice and arrangement of the insured, and which merely provides reimbursement for expense in excess of an initial fixed sum which must be met by the insured—does eliminate malingering and waste due to exaggerated trivialities, does provide security against the major financial hazards of sickness, and

is workable to the satisfaction of both the public and the professions. Combined, this principle of insurance with legal provision of prompt, adequate care for the *public wards* (destitute) (1), Financed Credit and deferred payments (Washington, D. C. and Pino plans) (9), and Compulsory Savings (2), a well rounded program for the provision of professional care of all the people of the State, with fairness and equity to all, is complete. (4)

11. Co-operating with our neighbors in Philadelphia and with the Pennsylvania, New Jersey, Indiana, Ohio and Michigan and other State Societies, the point-of-view of medicine has been made clear to certain Directors of well-known Foundations. Assurance has been received that financial and other support of such radical proposals as compulsory health insurance will not continue.

12. We believe it should be within the privilege, and, in fact, a definite function of this Committee to establish acquaintances with representatives of other similarly responsible and important organizations and groups.

13. The study and analysis of the "costs" incident to the maintenance of medical practice has not progressed beyond a considerable investigation and discussion of *method*. In February we reported to the Executive Committee "that the gathering of experience data from a sufficient number of physicians from which to draw dependable conclusions would cost in the neighborhood of four to five thousand dollars." Our budget of \$1,000, therefore, was inadequate. Upon our recommendation we were instructed by the Executive Committee not to proceed with the work until the House of Delegates could have the opportunity to further consider it.

Your Committee is of the opinion that the tangible benefits to be gained from such study probably do not justify the expenditure of the larger sum at this time. No part of the budget allowance of \$1,000 for this project was spent. Therefore, we now recommend the indefinite postponement of this study.

14. A sub-committee (Drs. Garen and O'Gorman) has begun the listing of all positions of a public or semi-public char-

acter, part or full time, which are or should be held by graduates of medicine, in the State, County, and City administrations. Pertinent details will be collected and tabulated. Probable maturity of this project: July 1, 1935.

15. The study of "medicine in industry" has been continued, but there are no details or recommendations for current report.

The sub-committee (Drs. Watson and Vogt) is compiling now a list of medical positions and opportunities in the industrial field.

Activity on "practice of medicine by corporation" has been toward the accumulation of further information. The New York Society of A.M.A. Approved Roentgenologists are preparing to test the Medical Practice Act regarding the legal status of lay technicians believed to be engaged in the practice of Roentgenology, by suing in the courts for an injunction.

16. Dean Charles K. Burdick, Cornell Law School, Ithaca, N. Y., has been appointed Chairman of a "Law Revision Commission" by Governor Lehman. Constructive criticisms and comments on the relation of physicians to court procedures should be addressed to him.

The Civil Practice Act has been amended (N. Y. Supplement, May 15, 1934, No. 5) to exempt physicians from the subpoena of an attorney, when medical services have been rendered in "a hospital, dispensary, or other charitable institution." Testimony may be taken by referee; except that when a copy of an order by the Court, where action is pending, is served with the subpoena, then the physician's attendance upon the trial is required.

17. We have undertaken to stimulate *economic thinking* by the circulation of reprints and other matter on general as well as medical economic topics, among which are the following:

(a) 200 books on "laws" (our own).

(b) A Study of Contract Practice and Dispensary Abuse—New Jersey.

(c) Four different discussions on "Meeting the Cost of Medical Care, Expense, Financed Credit" and "A Medical-care and Health Program for a Democratic State" (our own).

(d) The Epstein Bill—18 pages.

(e) Colorado State Resolutions on the control of the dole of free medical care.

(f) "The Basis of Recovery," an address of Dr. Virgil Jordan; through generosity of National Industrial Conference Board, Inc.

(g) "Will America Copy Germany's Mistakes?" by Hartz; through generosity of Pennsylvania Self Insurers' Association.

(h) Resolutions and Declarations for Economic Recovery—National Association of Manufacturers; through generosity of the Association.

18. Each month we have dispatched a News Bulletin to the officers of each County society, chairmen of local economics committees, officers of the State Medical Society, and others who have co-operated actively with the work in hand. (The wish for such was expressly voiced at the annual meeting of the County Secretaries at Albany in September.) The JOURNAL and minutes of our own Committee meetings have kept the County Societies informed of our activities. We believe these have been well worth the expense and effort.

19. The Committee has fulfilled its duties whenever called upon for "Economics" in the County Society programs and at the District Branch meetings. Since the establishment of the Public Relations Bureau, it has been our policy to accept invitations for public (lay audience) appearance only in co-operation with and subject to their authority and advice.

The Committee has held seven all-day sessions, supplemented by active correspondence. Each member has given generously of his time and effort to sub-committee details.

20. The volume of our work may be inferred from these statistics: Mimeographed material—25,000 pages in 200 loose-leaf books; 36,000 pages in some 40 circulars. More than 2,000 individual letters in answer to inquiries and in the other correspondence incidental to the furtherance of our Committee projects.

21. *Acknowledgments:* In the study of hospital economic problems the Committee has enjoyed the valuable assistance of Mr. L. M. Arrowsmith, Mr. S. L. Butler, Dr. T. D. Buchanan, Dr. C. H. Goodrich, Dr. C. A. Gordon, Dr. C. G. Heyd, Dr. R. Kovacs, Dr. H. M. Her-

ring, Dr. M. Lederer, Dr. F. MacCurdy, Dr. W. J. MacNeal, Mr. C. Norris, Dr. M. M. Pomeranz and Dr. T. D. Sloan, who have served on special sub-committees.

In the past reports of this Committee it has been customary to enumerate the regularly received bulletins and journals. This year these have come in such number that space does not permit individual enumeration. We have read them all with profit. The wide range spirit of co-operation in this field of medical rela-

tions augurs well for the future.

REPORT OF COMMITTEE ON ARRANGEMENTS

To the House of Delegates; Gentlemen:

Your Committee on Arrangements for the Albany meeting of the Medical Society of the State of New York has secured the use of the State Capitol for the scientific meeting place. All the sections will be under one roof, and on two floors, easy of access. This includes the Senate and Assembly Chambers. The rooms are all large, and it would be possible to take care of an extraordinary meeting. The Assembly Chamber will be used on Tuesday and Wednesday afternoons for the general sessions.

Meeting of the House of Delegates will be called at 10:00 A.M., Monday, May 13, 1935, at the Hotel Ten Eyck, the headquarters of the Society. The Technical and Scientific exhibits will be at the Ten Eyck. The Delegates dinner will be held at that hotel on Monday evening.

The Annual Dinner of the Society will be held at the Ten Eyck on Tuesday evening. Dr. Arthur J. Bedell, President of the Society, will preside. Governor Herbert H. Lehman has signified his intention to be present, if he is within the State. The Mayor of the City of Albany will welcome the Society. Dr. Walter L.

Bierring, President of the American Medical Association, will be present. Dr. Olin West, Secretary of the Association, will also be present, as will the Presidents of the State Societies of the surrounding States. A nationally known after-dinner speaker with a message will address us.

It is earnestly hoped that reservations for the Annual Dinner will be made as early as possible, so that your committee will know how many to provide for. Those wishing table reservations for their own parties will be accommodated in the order in which such reservations are received. Tickets will be \$3. Dr. Edgar A. VanderVeer, 28 Eagle Street, Albany, N. Y., the Chairman of the Dinner Committee, will have charge of the reservations and tickets.

There will be ample hotel accommodations for all.

The Ladies will be specially entertained by the newly organized Ladies Auxiliary of the Albany County Medical Society, in conjunction with your Committee.

Respectfully submitted,
 FREDERIC C. CONWAY, *Chairman*
 April 1, 1935

REPORT OF COMMITTEE ON PUBLIC RELATIONS

To the House of Delegates; Gentlemen:

Your Committee on Public Relations has met eight times during the present fiscal year in an endeavor to plan its activities and care for the various maladjustments that seem to develop between medicine and those other agencies, lay and governmental, that are actively interested in health matters.

All members of the Committee have given liberally of their time and been

most enthusiastic in developing the plans and policies of the Committee to endeavor to place organized medicine in its normal position of leading in the activities that have to do with the health of the people of the State. The work of this Committee consists of conferences and discussions with other State-wide groups working in the domain of health and in activating our County medical societies, especially their public relations com-

mittees, to function and carry on the activities in their respective Counties.

The experience of the Committee on Public Relations for the last seven years shows that the best way to work out problems between the profession and official and unofficial agencies is by conference and open-mindedness. The use of this method has usually resulted in a satisfactory understanding. The Committee has always been met at least half-way in conferences with departments of the State government and voluntary agencies. The Committee believes that a spirit of defense and belligerency is unnecessary. In conference there has always been a recognition of the essential factor of medical service in all health activities and that the profession of medicine was the only authoritative source of medical knowledge. The Committee believes that the administration of health and welfare laws may be made reasonably satisfactory to the profession by organized medicine through its Committee on Public Relations seeking conference, and then stating its position as to the administration of these laws.

The Committee believes that a satisfactory understanding can be reached much better by conference than by controversy. Whenever this plan has been used in the local administration of public health and welfare laws, it has usually resulted in establishing a relationship satisfactory to the local profession. The Committee believes that the profession will get farther by conference and co-operation than it will by controversy and belligerency; that if these methods are generally adopted public opinion will support the present position of medicine. This Committee believes that at least a part of the situation confronting the profession of medicine is the profession's fault to a larger extent than is generally recognized by the profession, and that misunderstandings may be more easily cured than it thinks.

The Committee has found that every department of the State government and voluntary agencies has been willing to confer, that they have been appreciative to consult organized medicine, and willing to give and take in the differences of opinion so as to reach a common ground. The Committee believes, after

years of experience, that if medicine approaches official and unofficial agencies, and particularly health and welfare agencies, in a spirit of opposition or too great rigidity of demand it will advance State interference in the practice of medicine. On the other hand, a spirit of conference and co-operation will advance leadership and control in local public health and welfare administration; examples of these statements exist in several places in New York State where the local profession is satisfied with its relationship to these agencies; relationships arrived at by making full use of the spirit of conference to remove misunderstandings.

There are tangible and intangible—visible and invisible—forces at work today in efforts to bring about so-called social betterment. Some of these forces perhaps are moving toward a new economical order and perhaps are more subtle than we have realized.

The real avenue to a solution of the problems confronting the practice of medicine lies in an understanding of the responsibilities of organized medicine.

One important thing that our Committee has been doing is to instruct medical students in their duties to organized medicine and its problems. We believe that many of medicine's present difficulties would never have originated if more of the young men in medicine were actively at work in their County medical societies, and took a greater interest in our State meetings and were initiated earlier into the various activities of our State Society. The average young medical man is not now interested in the problems of his profession because he learned little about it during his school years and does not, sufficiently early, become active in the work of his County medical society. Furthermore, such a group sharing in the work and control of our State Society would make it more elastic and adaptable to present-day demands, and the organization would find it easier to advance the present-day attitude of medicine.

Medicine must develop a co-operative spirit. We should meet those who have constructive suggestions in a respectful and tolerant spirit.

No individual and no group can be self-sufficient in this world. Medicine

must come to understand the need for co-operating its efforts with the efforts of many other groups in the struggle for the advancement of health conditions. Medicine must co-operate with those who offer anything of value in the struggle for betterment and this co-operation is as vital to our welfare as it is to the welfare of the rest of the world.

We will never win victories by just thinking about them. It is necessary to show the government of New York State that State Medicine is not needed. We should be able to do this by closer contact with departments of the State government and with the Governor of the State regarding future practice of medicine and the reasons why organized medicine takes a positive stand against state or socialized medicine.

This committee should study all relief projects that may be advanced for the purpose of determining their influence upon the practice of medicine.

The Sub-committee on the Deaf and Hard of Hearing has suffered the loss by death of its interested and active chairman, Dr. Wendell C. Phillips. This being a dual committee of the Committee on Public Health and Medical Education and the Public Relations Committee, it has been arranged by Dr. Farmer and this Committee that the Sub-committee shall continue its work under the chairmanship of Dr. Augustus J. Hambrook, of Troy, Dr. Fairfax Hall, of New Rochelle, being the other member; that they shall co-operate with the Medical Inspection Bureau of the Department of Education and the New York League for the Deaf and Hard of Hearing. This Sub-committee is gradually accomplishing a very beneficent piece of work and its co-operation with other agencies and the otologists of the State will, we hope, eventually lead to improved conditions and better care for those handicapped by deafness or difficulty in hearing.

The two objectives of the Committee, as stated in our last report; viz., raising the standard of otological care of children in schools for the deaf, secondly, working for conservation of the hearing of all school children, have been developed; and I feel already they are beginning to have results. In our last report we stated that the deaf schools of the State, seven

in number, have approximately 1,700 children, and we are reliably informed that an examination by an otologist is now required before entrance to a school for the deaf, and that many of these schools are giving more attention to the ears of their pupils.

This year the Committee has developed more fully its second objective, i.e., the conservation of hearing of all school children. This is a real problem, when we consider that in the schools of the State, we have over 3,000,000 pupils, and from reliable surveys made in several schools, where the audiometer was used to determine acuity of hearing, from 4 to 10 per cent were found with some degree of impaired hearing. Not enough of the audiometers are available in the schools, and the medical school examiners are thus handicapped in their work. Conferences have been held with Dr. Lewis A. Wilson, Assistant Commissioner in charge of Special Education; Mr. Joseph Endres, Chief of the Bureau of Handicapped Children; Dr. D. F. Smiley, Chief of the Medical Inspection Bureau; Dr. Thomas Parran, Commissioner of Health; Dr. Paul Brooks, Deputy Commissioner of Health; and Dr. Walter Craig, all with the object of evaluating the work and correlating plans for more effective methods for further diagnosis and treatment of children found with hearing losses.

Our work should consist in finding out the number of children with impaired hearing, the treatment and correction, as far as possible, of the hearing losses, and the placing in hard of hearing classes of all children, with hearing losses sufficient to warrant such instruction. The Education Law provides that where ten or more children are in need of such instruction, special provisions are made for teachers in lip reading and other improved aids, thus giving to this class of handicapped children the education, which is their right. Conservation of the hearing is at the same time being effectually carried out. The younger the child, the better will be the results, as during the first six years of life, the ear is developing from infantile to adult, and is more susceptible to infections and possible hearing losses.

We must teach the need of oral hygiene, the isolation of all cases of in-

fection of the upper respiratory region, and the prompt treatment of ear complications when they occur. The County Medical Society can be of the greatest help to the Education and Health Departments by co-operating with Parent and Teachers groups, League for Hard of Hearing, and others interested in disease prevention and conservation of hearing.

We have not been content this year with the school child, but have as well considered the preschool child. Dr Fairfax Hall, a member of the Committee and chairman of the committee on preschool examinations of the New Rochelle Medical Society, has started what we think is a fertile field in the early care of preschool children. In Westchester County examinations were made by the family doctor, at pry clinics, and free clinics. Publicity was given through the newspapers, and it is felt that the result of this work is a very valuable public health measure. Many conditions were brought to the attention of the parents, which, given suitable care, will be helpful to the child's proper development and good health. Especially is this true of the infections of the upper air passages and ear infections. As it is during the first four to six years of life that many of these infections of the ear occur, and if not recognized and properly treated, serious hearing losses may be the result.

Doctor Hall should be commended for taking the initiative in this very important work, and we hope to see other County Medical Societies take similar action. The County Medical Society should recognize the great importance from the standpoint of the correct and early diagnosis of hearing defects, both in the preschool and school child and through the early diagnosis and treatment, the conservation of hearing of thousands of our school children will eventually follow. The Subcommittee favors the enactment of uniform State legislation requiring all doctors to report to the State Board of Education each and every case of partial or total deafness among children 16 years and under, met with in the course of their professional practice.

The Subcommittee is especially indebted to Dr Joseph S. Lawrence, Executive Secretary of the Medical Society of the State of New York, for his untiring

efforts and co-operation with the Committee. To our secretary Miss Samuelson, the Subcommittee can truly say, that her work made possible the results obtained. She will be in charge of an Exhibit for the Deaf and Hard of Hearing, at the State Society meeting at Albany.

Members of the Committee have appeared before medical groups, the New York conference on Social Work, Parent-Teachers Association, service clubs, and other organizations. Subcommittees have been formed in each County Society, articles written for journals on conservation of hearing, and other ideas undertaken, such as the Exhibit to be held in Albany at the meeting of the State Society. Present laws may make funds available for the correction of conditions causing the hearing defects in indigent cases. Several new bills have been introduced in the present session of the Legislature towards more thorough school examinations. The Committee has been in constant touch with the Legislative Committee of the State Medical Society. If we all work together, conservation of hearing in our school children will be a reality.

A ruling by the State Department of Education whereby crippled children coming under the provisions of the Handicapped Children's Law can only be admitted to hospitals, which have made arrangements for carrying on the general education of the child whilst under surgical care and which have a Physio-Therapy Department, is definitely to the disadvantage of the surgeons of the State as it relegates these children largely to State-controlled institutions when as a fact a large proportion of such crippled children can be satisfactorily cared for in their own County by the private surgeons of their vicinity.

Conferences with representatives from the Department of Education and the Department of Health have resulted in these restrictions being removed in all such cases of crippled children where the condition is remediable within a period of two to three months. This makes it possible to care for most of the crippling conditions of children in their own County and by their own surgeon, who is compensated for his services under State aid.

It seems most unfortunate that more of the surgeons of the State, especially those doing orthopedic work, do not avail themselves of the opportunity presented to care for such cases under the provisions of the Handicapped Children's Law. It would seem as though there should be one or more surgeons in each County who will undertake this type of work and enable the crippled child to be cared for in his own neighborhood and by a surgeon of the vicinity rather than by one in the employ of the State. Neglect upon the part of our surgeons to avail themselves of the provisions of this law, obtain court orders and do the necessary surgical work in the various hospitals throughout the State is resulting in a great economic loss to the profession and gradually fostering the development of State Medicine for the Crippled or Handicapped child.

Your Committee notes with satisfaction the progressive spirit of advancement shown in certain County medical societies where the medical profession are co-operating with other agencies and establishing a higher grade of medical practice especially with reference to Public Health and the prevention of disease. In many instances this is being accomplished without sufficient paid executive force and through the untiring efforts of high-minded medical men who are sacrificing themselves in a heroic effort to raise the standard of medicine in their County.

Other County medical societies are raising their standard and meeting present-day requirements by employing executive secretaries who relieve the medical men of much of the detail administrative work connected with the carrying on of a proper program of medical leadership.

This Committee recommends to the House of Delegates that some plan should be considered which would encourage more of the County medical societies to employ full-time paid executive secretaries with centralized office and equipment so that all medical problems could receive *prompt attention*, medical bulletins published, and the membership kept informed and activated on all questions appertaining to present-day practice.

Your Committee is impressed with the necessity of its being provided with a

sufficient budget allowance to permit it to have a full-time Field Secretary who shall be constantly at work throughout the State assisting the County Society Public Relations Committees to develop their programs and put into execution the activities which this Committee develops. The salary and expense of such paid field worker would be approximately \$5,000 per year. Such expense is especially warranted in these times when co-operation with other agencies is most essential to demonstrate to the public that medicine is doing its part in endeavoring to distribute to all of the people the benefits to be derived from the advances in the science and art of medicine. This suggested expenditure should be given careful consideration by our Trustees.

Inasmuch as this Committee is for conference with other agencies, official and unofficial, and has no power to make final decision upon the various problems arising throughout the year, it is suggested that the Chairman or his designated representative, be invited to attend the meetings of the Executive Committee in order that a full and free explanation of each subject can be brought to the Committee. Resolutions and reports are frequently not sufficiently explanatory and may not give the correct viewpoint of the situation. This is simply another example of the necessity of conference and co-operation, but within our own ranks. The experience of this Committee over the past seven years would indicate the necessity of eliminating some of our fixed ideas and becoming more open minded and constructive in our internal and external affairs. We should develop our State Society and County units upon such a high standard of efficiency as to forestall any and all efforts that tend to socialized or State medicine.

We wish to express to our Secretary, Dr. Ross, and to our Executive Officer, Dr. Joseph S. Lawrence, our keen appreciation for their interest and untiring efforts in behalf of the work of the Committee. The work of the Committee has been constructively advanced by the wise counsel and advice of our President, Dr. Bedell, and our Secretary, Dr. Dougherty. To Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and

Medical Education, who has been most co-operative and helpful, the Committee desires to extend its gratitude and appreciation.

Respectfully submitted,

J. E. SADLER, *Chairman*

April 1, 1935

REPORT OF COMMITTEE ON MEDICAL RESEARCH

To the House of Delegates; Gentlemen:

In behalf of your Committee on Medical Research, I have the honor to present the following report.

The opposition to medical research in this State has been unusually quiet during the latter half of 1934. The concentrated efforts of the antivivisectionists during this time were directed in an unsuccessful campaign elsewhere.

It was not until February 28 that Mr. McDermott introduced the annual antivivisection bill, Assembly Int. 1863. Immediate steps were taken to inform the members of the codes committee that similar bills had been introduced for the last five years with no adequate reasons for their adoption. In public hearings at Albany on these bills the antivivisectionists had produced no evidence that the present laws were ineffectual. Many prominent citizens all over the state wrote to the members of the committee protesting against the McDermott bill, No. 1863. The result was that the assembly com-

mittee defeated this bill in the meeting on March 12. Consequently, it was not necessary to call upon those members of the medical profession who annually sacrifice their valuable time in an excursion to Albany to appear personally against the antivivisection bill.

The American College of Surgeons, unaware of the fact that New York State has had an active functioning committee for many years, appointed a separate committee to act against the antivivisectionists in this State. Your chairman succeeded in keeping this committee inactive as it was considered dangerous to have disconcerted action which might do more harm than good.

Your chairman wishes to thank the members of the Assembly Codes Committee for their intelligent action in defeating the McDermott bill, Assembly Int. 1863.

Respectfully submitted,

JOHN J. MORTON, *Chairman*

April 1, 1935

REPORT OF BOARD OF TRUSTEES

To the House of Delegates; Gentlemen:

The Board of Trustees has held no regular meetings during the past year, but has assembled on call of Chairman, whenever there was business to be transacted, or matters of policy to discuss. Several special meetings of the Investment Committee have been held.

It is a satisfaction to be able to report that the funds of the Society are invested in the soundest securities that could be obtained. The securities have been kept under careful review, and we have had, from time to time, the advice of financial experts. In investing funds of the Society, we have aimed, first, at security. There has been depreciation of some of the bonds, but the present values of most of our holdings show an advance in the present market.

The Trustees have had excellent advice and co-operation from the Treasurer, in

dealing with financial matters. The Treasurer embodies in his report the details of the finances of the Society, and it would be superfluous to duplicate the details in the report of the Trustees.

The Society is fortunate in having income producing funds, which enables the organization to exert its influence in the betterment of health and well-being of the public through its membership.

The budget, as presented by the Executive Committee, was given careful study, and approved, with but few modifications.

It has been the policy of the Trustees to exercise as close economy in expenditures as is consistent with efficient function of the various standing and special committees, as well as the performance of the duties of the various officers.

Respectfully submitted,

GRANT C. MADILL, *Chairman*

REPORT OF BOARD OF CENSORS

To the House of Delegates; Gentlemen:

There has been held during the year but one session of the Board of Censors.

The Board convened in the offices of the Society, 2 East 103rd Street, New York City, on Wednesday, June 20, 1934, at 10:30 A. M., to hear the Appeal of Dr. Fred Houdlett Albee against the action of the Medical Society of the County of New York suspending him from the rights and privileges of membership for the period of one year.

The following Censors were present: Richard H. Sherwood, Louis A. Van Kleeck, Clark G. Rossman, C. Knight Deyo, Alfred C. Bates, William A. Groat,

and Raymond G. Perkins; Arthur J. Bedell presiding; Daniel S. Dougherty, Secretary.

The appellant was represented by Mr. Lloyd Paul Stryker; the respondent by Mr. Reed B. Dawson; Mr. Lorenz J. Brosnan acting as legal advisor for the Board.

After careful consideration of the discussion and the evidence presented the Appeal was denied and the action of the Medical Society of the County of New York upheld by a unanimous vote.

Respectfully submitted,

DANIEL S. DOUGHERTY, *Secretary*
April 1, 1935

REPORT OF THE COUNSEL

To the House of Delegates; Gentlemen:

Your Counsel herewith submits his report of the activities of the Legal Department of the Medical Society of the State of New York for the period from March 1, 1934, to and including February 28, 1935.

What we have said in previous reports with respect to the activities of our Department applies with equal force to the present reporting period. The past year has been an exceedingly busy one both in court and in consultation. A report contains only conclusions. It does not give any adequate picture of the work involved or the responsibility assumed by our Department.

Your Counsel has greatly enjoyed his association with your officers and committeemen. It requires contact with them to realize the splendid work they are doing for the members of your Society in connection with the important problems that confront organized medicine. Your Counsel wishes to express his appreciation to these gentlemen for their assistance and co-operation.

In making his report your Counsel adheres to the convenient category employed in previous years whereby his activities have been divided into three main divisions: (a) The actual handling of malpractice actions before courts and juries and in the Appellate tribunals; (b) counsel work with officers, committees and individual members of the Society;

and (c) legislative advice and activities.

Litigation

Once again your Counsel is pleased to be able to report in the field of litigation the splendid work of his associate, Mr. William F. Martin. Mr. Martin enjoys the respect and confidence of the judges throughout the State and on many occasions they have spoken to me most favorably about Mr. Martin's high character and his splendid ability as an advocate. Similar expressions have come from many members of your Society with whom Mr. Martin has come in contact either in court or in consultation.

Excellent work has also been done by your Counsel's associate, Mr. Thomas H. Clearwater, the attorney for the Society.

Your Counsel has reason to be proud of the splendid spirit of loyalty and devotion manifested by his entire staff, both legal and clerical.

With this preliminary statement we note that there were commenced in the present *twelve-month* reporting period 232 actions as against 230 actions during the previous *thirteen-month* reporting period. These actions do not include a large number of claims in which we were successful in persuading the claimants or their attorneys not to bring suit. There remain a number of claims outstanding in which suit may ultimately be brought. Of the 201 actions disposed of during the reporting period, 39 have been settled.

In 156 actions we have obtained judgments for the defendants after trial, or they have been disposed of through dismissal, discontinuance, or abatement. In 6 cases judgments were rendered in favor of the plaintiff. Of these cases 2 are now pending in the Appellate Division.

In the Appellate Division of 5 cases appealed 3 were won and 2 were lost.

We note from Table I that there are now pending 625 cases.

In connection with the subject of litigation it is in point to note that the Society has had in operation for over a decade a group plan of insurance which affords the members an opportunity to protect themselves against the hazard of litigation.

The Insurance Committee of the Society is composed of Dr. Charles H.

Goodrich and Dr. Samuel J. Kopetzky. This committee representing your Society has held a number of meetings in the past year in connection with questions that are before them for consideration. Mention should be made of the splendid work which they are doing for the members of your Society.

Table II gives a comparison of the number of members insured in 1932, 1933, 1934, and 1935, and the number of members in the County societies, and the percentage of insured members in the County societies, and in the entire State Society. The figures are sufficiently clear to obviate the necessity of extended comment.

Counsel Work

During the period of this report, your

* A = number of members in County Society; B = number of members insured; C = percentage insured.

Counsel has prepared for publication in the Society's JOURNAL articles in the nature of editorial comment. These editorials have included the following:

Consent to Operation—An Interesting Case.

Evidence—Tests to Determine the Truth or Falsity of Testimony.

Charitable Hospitals—Exemption from Liability for Negligence of Nurse.

Physician and Patient—Duty to Warn Patient of Dangers Incidental to Operation.

Physician and Patient—Waiver of Privileged Communication.

Malpractice—A Gratifying Decision by an Appellate Court.

Death Action—Physician's Responsibility. Chiropactors—Illegal Practice of Medicine.

Death by Accident or Disease.

Revocation of Physician's License—Unprofessional and Dishonorable Conduct.

Illegal and Fraudulent Practice of Medicine.

Operation, Foreign Body—Responsibility of Surgeon.

Charitable Hospitals—Liability for Suicide of Patient.

Civil Liability of an Unlicensed Practitioner.

Responsibility of Physician for Negligence of Dentist.

Health Officers—Court's Construction of Powers.

Illegal Practice of Medicine—A Quack is Convicted of Manslaughter.

Physicians—Liability for Acts of Substitute Physicians.

Operation without Consent—Surgeon's Right to Operate in Emergency.

Tonsillectomy—Claimed Negligence in Connection with Operation.

Your Counsel has also digested and there have been published in the STATE JOURNAL case reports upon malpractice actions which it has been felt were of special interest to the members of the profession. The case reports published during the previous year are as follows:

Erysipelas Alleged to Have Resulted from Doctor's Negligence.

Alleged Negligence in Appendectomy.

Death Claimed Due to Delayed Operation.

Death Following the Extraction of Teeth.

Treatment of Warts.

Claim of Negligence in Tracheoplasty.

Claim of Negligence in Connection with Use of Lane Plate.

Explosion of X-ray Tubes.

Claimed Negligence in Performance of Herniotomy.

Death from Peritonitis.

Treatment of Lacerated Hand at Clinic.

Claimed Negligence in Performing Tonsillectomy.

Plastic Surgery on Nose.

Treatment of Laceration of Thigh.

Burns Due to Bandage Catching Fire.

Claimed Failure to Detect Glaucoma.

Failure to Determine Presence of Particle of Glass.

Claimed Failure to Detect Bullet in Finger.

Loss of Eye Caused by Infection.

Alleged Negligent Treatment of Cat-Bite.

Death of Infant Following Delivery.

Claimed Fracture of Hip as Result of Fall from Hospital Bed.

Claimed Failure to Remove Rubber Drain.

Treatment of Obstructed Tear Duct.

Claimed Negligent Appendectomy.

Claim of Improper Amputation of Fingers.

Death of Patient Following Cholecystectomy.

Alleged Negligent Treatment of Ischio-rectal Abscess.

Claimed Negligent Operative Treatment of Muscular Dystrophy.

Claimed Injury to Uvula.

Amputation of Leg Subsequent to Herniotomy.

Alleged Diathermy Burn.

Plastic Operation on Nose.

Alleged Negligent Removal of Tonsils and Adenoids.

Broken Screw in Leg.

Your Counsel is pleased to learn from the members of your Society that they find these reports and editorials interesting and instructive.

In addition to his other duties, your Counsel receives frequent requests for opinions on various subjects. It should be remembered that the Executive Committee of your Society has ruled the requests for legal opinion, whether coming from individual members of your Society or from component County Societies, must in the first instance be referred to that body for action. If the Executive Committee deems the inquiry a proper one for opinion by the Legal Counsel, it refers the same back to him for reply. Some of the matters upon which advice has been thus rendered are the following:

1. Communication from a physician on

behalf of a Hospital Staff concerning the responsibilities of supervising surgeons in the following instances:

(a) Liability of supervisor who participates in no other way than as observer in the operation performed.

(b) Liability of a hospital for acts of a doctor performing an operation who has not been granted full privileges, but only to demonstrate his qualifications under supervision.

(c) Liability of supervisor in case he displaces an operator under his supervision who is deemed unable to cope with the situation at hand.

2. Inquiry from a physician as to necessity for hospital physiotherapist to be licensed by the State of New York and as to liability of a physician referring cases to hospital physiotherapy departments in cases of patients receiving burns during treatment.

3. Communication from an attending physician on a hospital staff, with a graduate interne on his service, who carries out treatment under his supervision, inquiring as to necessity for the attending physician to be present during the performance of blood transfusions or other intravenous therapy, and as to the legal responsibility in such cases of the attending physician and of the hospital.

4. Inquiry from a physician as to the legality of a hospital or a layman employing a physician as a pathologist and making charges for his professional services, which services include the making of diagnoses, giving of prognoses and the prescription of treatment, and whether the practice of pathology as mentioned above constitutes the practice of medicine.

5. Inquiry from a physician as to the legal responsibility of an operating surgeon in the event that some accident should occur during an operation, such as a miscount of sponges:

(a) When a graduate nurse is present;

(b) When an undergraduate nurse is present.

Further inquiry as to whether the patient could take action against the hospital.

6. Communication from the superintendent of a hospital requesting an opinion relative to the responsibility of a hospital and its physicians in connection with certain proposed laboratory work.

7. Inquiry from a physician as to the legality of a contract entered into between physicians restricting the practice of medicine.

8. Inquiry from a component County Society requesting information as to the following:

(a) What licensing requirements cover the operation of institutions for the care of alcoholics.

(b) If such an institution is run by a lay individual, what provision must be made for medical supervision.

(c) Is the routine care of alcoholics considered medical practice which must be performed by a licensed physician?

9. Communication from a physician inquiring as to his right to testify in court regarding a former patient.

10. Inquiry from a physician requesting an opinion as to whether when in the course of pregnancy a physician finds symptoms appearing that the fetus has died, he is obliged to call in another physician to agree with him that the fetus is dead before he may legally proceed to abort or induce labor.

11. Inquiry from a component County Society as to whether a physician who is employed on a salary basis by a welfare organization may be barred from membership in a County Society.

12. Inquiry from the superintendent of a hospital inquiring as to the legal responsibility of the hospital and a physician appointed to supervise nurse anesthetists in the event of negligence on the part of the nurse anesthetists.

13. Inquiry from a physician who has made a physical examination of a claimant at request of a company against whom claim was made, as to his rights to reveal to the company information concerning the claimant, obtained upon treating the man years before.

14. Communication from a physician requesting information concerning patients treated under the Welfare Laws:

(a) Is a physician responsible to the patient (or to the patients family) or the Welfare officer in advising the nature of treatment?

(b) Who is legally responsible for the outcome of a medical or surgical welfare case where treatment advised by the physician is refused or not authorized by the Welfare officer and where, later on, it is shown that the lack of treatment advised has prejudiced the recovery of the patient?

15. Inquiry as to the criminal and civil liability of a physician who accedes to the request of a patient, that her fallopian tubes be cut to prevent further pregnancies, during the performance of an abdominal operation.

16. Inquiry from a physician as to the legality of action by local school authorities, appointing a physician, other than a health officer, to make examinations of school children.

17. Inquiry from a physician for an opinion concerning the following problem:

(a) In the case of a patient adjudged mentally defective and already committed to one of the State institutions for the care and treatment

of mental diseases, what responsibility would rest on the shoulders of a private hospital accepting the previous patient of a State institution for mental disease by transfer?

(b) Would the opinion of the physician in charge of the patient in this private institution be final as to whether or not the patient was to be deemed fit at any given time for discharge?

18. Communication from a physician requesting an opinion as to whether or not he should be required to make known diagnoses or case histories of former patients who have afterwards applied for financial aid to welfare agencies, both governmental and private.

19. Inquiry from a physician as to the legality of male sterilization.

20. Inquiry as to whether the employment of a secretary, either on a percentage basis or otherwise, who engages in solicitation with various insurance companies on behalf of the physician, is in conflict with the principles of Professional Conduct of the Medical Society of the State of New York.

21. Communication from a physician on behalf of a hospital staff for an opinion on the following:

(a) Is a surgeon permitted to operate on an emergency case, when a patient is unconscious and unable to sign a consent, without rendering himself liable to a suit for damages?

(b) Must a patient be twenty-one years of age in order to give consent to operate?

(c) Is telephoned permission of a parent, witnessed and heard by a third party, sufficient?

22. A communication from a physician requesting an opinion in the following matter concerning professional ethics: A surgeon, a member of the attending staff of a hospital, has referred to him for operation a patient sent by an osteopath. Post-operatively the osteopath visits the hospital and with the consent of the surgeon, administers treatment, consults the charts, etc.:

(a) Is the attending surgeon within his ethical rights when he permits the procedure outlined?

(b) Is the hospital within its rights to refuse permission for the osteopath to administer treatments to a patient while hospitalized?

23. Inquiry from a physician asking for an opinion relative to the existing statutes forbidding or permitting the sterilization of humans.

In addition to the foregoing your Counsel has been asked to render advice and consider the following:

24. Inquiry from a component County Medical Society asking for an interpretation of the Civil Practice Act in so far as it relates to the power to compel, by the service of a subpoena, a physician to give

testimony regarding a patient he has treated in a hospital.

25. Inquiry from a component County Society asking for advice as to the steps necessary to prevent a physician who has been convicted and sentenced to prison, from being reinstated to practice medicine.

26. Inquiry from a member of a hospital staff asking for opinions on the following:

(a) Who is the legal owner of hospital records?

(b) Who has the legal right to subpoena hospital records in a lawsuit, the defendant or the plaintiff?

(c) Is it legal for records to be subpoenaed subject to telephone call?

(d) Is it legal to remove any part of a record from the chart before allowing it to be copied, or after it has been subpoenaed by the court?

(e) Is an attorney who holds a signed and notarized authorization from the patient permitted to see and copy all records pertaining to said patient's stay at the hospital?

(f) Is it legal for a lawyer representing an insurance company to be permitted to see said records without an authorization from the patient?

27. Inquiry from a physician on behalf of associate physicians who are established in common offices, using a common system of bookkeeping and who carry individual malpractice insurance policies as to the necessity of carrying a policy covering them as a group.

28. Inquiry from the Secretary of a component Medical County Society relative to the apparent abuse of the physician as a witness in court, with special reference to the rights of a physician when his testimony is in the nature of expert testimony.

29. Inquiries from physicians seeking information concerning decisions in the medicolegal articles in the JOURNAL.

30. Inquiry as to the legality of the practice by optometrists of removing foreign bodies from the eye.

31. Inquiry from a physician as to the advisability of signing an affidavit divulging information acquired in the course of professional treatment of a former patient.

32. Communication from a physician asking for advice in the following matter: A patient who had been treated by said physician in a hospital afterwards sued a public service corporation for damages, and said physician had been requested by an investigator to testify in court. Would said physician be guilty of breach of confidence if he so testified?

33. Communication requesting advice as to coverage under the group policy for acts of assistants:

34. Inquiry from a physician as to the extent of his rights and duties to testify

as to the fitness of a patient to assume the custody of his child.

35. Inquiry from a physician as to the extent to which a surgeon from a foreign country, not licensed in the State of New York, may engage in the practice of medicine in this State.

36. Inquiry from a physician as to the ethics of advertisements by physicians in the daily press.

Your Counsel acting with the Committee on By-Laws has examined the proposed amendments to the Constitution and By-Laws of a number of component County societies and has rendered advice and made suggestions in connection therewith.

Your Counsel has been in conference and consultation with the members of the Committee on Insurance with respect to various matters that have been referred to them for action.

Your Counsel has been in conference with the members of the Committee on Medical Trends and has prepared the existing contract entered into at the time of the formation of the Public Relations Bureau.

Your Counsel has also advised from time to time with the Chairmen and members of other standing and special committees of the Society.

Your Counsel has also rendered his assistance to the members of the JOURNAL Management Committee in the matter of

the applicability of the New York State Sales Tax to the NEW YORK STATE JOURNAL OF MEDICINE.

Your Counsel acted as legal advisor to the Board of Censors of the Society in connection with the appeal of Dr. Fred H. Albee from the disciplinary action of the New York County Society.

Legislative Advice and Activities

The present session of the Legislature has been an extremely busy one and many bills have been introduced of interest to organized medicine.

Your Counsel has drafted or assisted in drafting a number of bills introduced at the present session of the Legislature, and his opinion has been requested and given with respect to bills that have come before the Legislature affecting the medical profession.

Conclusion

Once again in concluding this report we do so by expressing our grateful thanks to the many members of your Society who have so generously given of their time and talents in assisting us in the defense of malpractice actions. Their co-operation and assistance are in no small measure responsible for the results shown by this report.

Respectfully submitted,

LORENZ J. BROSNAN, *Counsel*

April 1, 1935.

REPORT OF COMMITTEE ON CONSTITUTION AND BY-LAWS

To the House of Delegates; Gentlemen:

The Committee on the revision of the Constitution and By-Laws appointed by the Executive Committee begs leave to present the following changes:

Constitution

Article IV. Delete "(c) the Editor-in-Chief" and change (d) to (c).

By-Laws

Chapter I. Delete Section 5 and substitute: "Honorary members shall be entitled only to the privilege of attending and addressing the meetings of the Society. Retired members shall not be subject to assessment but shall be accorded all the rights and privileges of

active membership with the exception of voting or holding office."

Chapter II. Section 1—Delete the words "with voice but without vote" making the sentence read "(d) the past presidents and past secretaries of the Society who shall be life members."

Chapter VIII. Section 1—Second paragraph—substitute for the word "maintenance" the word "expenses" making it read "a per diem for expenses not to exceed fifteen dollars."

Chapter X. Section 5—second line—delete the word "ten" and substitute "twelve" making it read "The Committee on Economics shall consist of twelve members, including the Chairman."

Chapter X. Add new Section 15—

Completion of Work—in all cases where certain work is being performed or problems studied by Standing or Special Committees, such work or study shall not be considered finished when the tenure of office of such Committee ends but shall

be continued by the succeeding Committee.

Respectfully submitted,

FREDERIC E. SONDERN

SAMUEL J. KOPETZKY

DANIEL S. DOUGHERTY, *Chairman*

April 1, 1935

REPORT OF FIRST DISTRICT BRANCH

To the House of Delegates; Gentlemen:

On June 6, 1934, in New York City the Executive Committee of the Branch held a meeting to prepare the program of the annual fall meeting. The full Committee was present and after wide discussion it was agreed that "Medical Welfare Administration" should be the subject for the meeting. It was decided to have the meeting in Peekskill because of its central location and to begin the program at 4:00 o'clock to make it possible for more men to attend without too great a sacrifice to their work.

The annual meeting on October 24 was attended by a hundred members who were enthusiastic about the program.

Dr. Bedell, President of the State Society, gave the branch some very good points on how to evaluate some of the State Board of Health's report on infant mortality.

Dr. Lawrence, Executive Officer of the State Society, in a clear and concise form told of the method of administration of the TERA law. He showed many interesting slides to illustrate his points.

Following dinner Dr. Squire gave a most entertaining and enlightening address about some of his experiences as County Medical Examiner of Westchester. He stressed especially the need for censorship of the newspapers and movies, and urged the doctors to encourage such movements among the young people as the Boy Scouts.

A new activity, the result of a resolution of the Council, was launched on February 7, 1935. This project aims to bring together organized groups which exist within the First and Second Districts. A committee consisting of one member from each of the component County Societies of the First District was appointed by the President: Dr. Aaron Sobel, Dutchess-Putnam; Dr. Earl C. Waterbury, Orange; Dr. George M. Richards, Rockland; Dr. Edwin C. Podvin, the Bronx; Dr. Samuel J. Kopetzky, New York; Dr. William C. Buntin, Richmond; Dr. Walter W. Mott, Westchester.

This committee has met with a similar committee of the Second District Branch and Dr. Kopetzky and Dr. Waterbury have been appointed chairman and secretary, respectively. Three sub-committees, as follows, were also appointed: Socialized Insurance Questions: Drs. Warren, Sobel, Bauer; Industrial Questions: Drs. Podvin, Steffen, Buntin; Officials (Health, Insurance Company, State Board, School and Laboratory): Drs. Mott, Richards, Payne.

I wish again to thank all the officers and members of the First District Branch for their attendance and co-operation during 1934-35.

Respectfully submitted,

C. KNIGHT DEYO, *President*

April 1, 1935

REPORT OF SECOND DISTRICT BRANCH

To the House of Delegates; Gentlemen:

The component County Societies and Membership have exhibited during the past year an increasing interest and support in all activities of the Second District Branch. All regular and special committee meetings have had excellent attendance.

The Annual Meeting which was held at the Garden City Hotel, Garden City, November 15, 1934, had an attendance of more than two hundred. A complete report of the meeting has been previously published in the JOURNAL. [34:1036, 1934.]

The afternoon scientific session with

several very interesting exhibits proved to be a very popular feature and it is recommended that this be continued as part of the regular program of the annual meeting.

The Annual Dinner was likewise very well attended. The address, "Is the Physician Prepared?", which was delivered by the President of the Medical Society of the State of New York, Dr. Arthur J. Bedell, was a timely, thoughtful, and scholarly presentation and has stimulated careful consideration and comment. [For this address cf. JOURNAL 34: 993, 1934.]

Dr. Frederic E. Sondern, who had just returned from England, spoke on National Health Insurance in England. The facts presented with their possible relationship to impending National and State legislation, made his address of great interest and thought.

Mr. Mathew D. Woll, third vice-president of the American Federation of Labor, spoke on "Labor Looks at Medicine." Mr. Woll's address was carefully considered and most gratefully received. The Branch wishes to extend to Mr. Woll its sincere appreciation and gratitude for his efforts and time. It is hoped that many of his desires and recommendations may be realized in the relationship of organized labor and organized medicine.

Kings County has had an excellent scientific program of well-diversified subjects very ably presented. The standing committees have been most fortunate in the selection of their membership, and the results which they have accomplished have been of the greatest assistance, not only to the Society, but also to the Branch. The Society as a whole forms a well-constructed, carefully managed unit of organized medicine.

Queens County has been exceedingly successful during the year. A great deal of time and consideration have been given to scientific work, development of a Medical Library, and Postgraduate Medical Education. Here, again, most excellent work has been accomplished by the standing committees. The County Society has through delegated members developed the staff and medical management of the new Queens Borough Municipal Hospital which is about to be opened. The

Society is to be congratulated upon its attainment. The co-operation which has been shown in the work of the Branch is duly appreciated.

Suffolk County Medical Society has likewise devoted much effort to its scientific progress. The Medical Economics Committee reports that arrangements have been strengthened with the County Welfare Commissioner and the physician regarding the remuneration for the medical care of the indigent cases, and the arrangement is working out quite satisfactorily.

The Medical Economics Committee and Public Relations Committee have been meeting with some of the school boards to establish a uniform and satisfactory fee schedule for the medical examination of school children. A marked improvement has been noted. The Committees on Public Health and Graduate Medical Education have given their support to the enlargement of the County Tuberculosis Sanatorium, with the result that two new fireproof buildings are now under process of construction.

The Society has endorsed principles and fee schedules for the care of welfare cases. Its committee also recommends that an outline for postgraduate medical education be adopted, and that the State Department of Education appoint only members of a County Medical Society as school medical examiners.

The Suffolk County Health unit continues to function in co-operation and with the support of the County Society. Suffolk County Society has rounded out a year well identified by its medical economics, public health and public welfare work.

Nassau County has unquestionably had the most active year in its history. Never before has so much been accomplished as is now being accomplished under the present administration and was accomplished under last year's administration.

Legislation. Last year's Legislation Committee established a precedence by sending a letter to the candidates for major offices who were in position to influence legislation favorably or unfavorably to the profession, asking their attitude on basic legislative problems.

This year's Legislation Committee has established strong contact with the various legislators.

Public Health. The Public Health Committee has continued its diphtheria preventive activities and is now engaged in a quiet campaign to promote the use of the Sauer vaccine against whooping cough with the idea of laying the foundation for some later activities along this line directed to the lay public.

Professional Advisory Committee. Since July of last year the medical profession has had an opportunity to assist in the determination of policies in the matter of medical relief to the indigent. Many improvements have been effected in the local situation by clearing up misunderstandings and eliminating unnecessary routine.

Medical Economics. This committee sponsored an open meeting in December of last year which was very well attended by society members and resulted in a frank and profitable discussion of many economic problems. This year the committee has been most active and is succeeding in several quarters in solving some of the problems of the clinic and other economic matters of interest to the profession.

Postgraduate Education. Aside from the scientific session of the Society,

arrangements have been made in the last year to have a general invitation extended to all medical men to attend the staff meetings of each of the hospitals in the County, and notices of these meetings have been included in the monthly publication. The major postgraduate opportunity is the Nassau County Tumor Clinic which was organized on a co-operative basis by the Society and the lay committee of the American Society for the Control of Cancer. The clinic continues to see about thirty new patients per month, all of whom are referred by practicing physicians, and has continued to hold weekly conferences open to any physician, where the new cases are discussed and interesting follow-up cases are presented for study.

Membership. The Society has succeeded admirably in retaining its members in spite of the financial difficulties.

In conclusion the President wishes to extend to Dr. Alec N. Thomson, the Secretary and Treasurer of the Branch, his thanks and appreciation for the work and keen interest and thoughtful advice and consultation which he has so cheerfully given.

Respectfully submitted,

LOUIS A. VAN KLEECK, *President*

April 1, 1935

REPORT OF THIRD DISTRICT BRANCH

To the House of Delegates; Gentlemen:

The Third District Branch, which is composed of the Counties of Albany, Columbia, Greene, Rensselaer, Schoharie, Sullivan, and Ulster, comprises an area of over 125 miles long and 70 miles wide having a membership of 562.

With the evident changing relationship of the medical profession to the public and to the State, it would seem that the District Branch will be needed more than ever as the connecting link between the Medical Society of the State of New York and the County Medical Society.

The address, given by Arthur J. Bedell, M.D., President of the Medical Society of the State of New York, at the Annual Meeting of the Third District Branch, was evidence of the clarifying, useful, and valuable application of this relationship to the profession.

In compliance with a resolution by the Council on December 13, 1934, a co-ordinating committee of the Third District Branch has been appointed. It has seemed best that this committee be composed of all the presidents of the County societies of the Third District Branch with the President of the Branch as the chairman.

There have been no differences to be composed and the profession of this District as a whole are of one mind and not at variance with the views of the State Society.

At the request of the Committee on Trends in Medical Practice of the State Society, the Third District Branch has appointed within the district a small committee on Trends in Medical Practice.

Some County societies of the Third District Branch have availed themselves

of one or more of the postgraduate courses offered by the Committee on Public Health and Medical Education of the Medical Society of the State of New York. These rural Counties are hopeful that this activity of the State Society will be continued.

Throughout the Third District there has been greater activity than ever in pre-school vaccination, immunization and physical examinations and the T. B. testing of school children of high-school age.

Albany and Sullivan Counties have had meetings at which there have been guest speakers of prominence.

The symposium on the Columbia County Health Unit presented at the annual meeting of the Third District Branch and published in the JOURNAL issue of December 15, 1934, evidently created much interest and favorable comment. The JOURNAL of October 15, 1934, commenting on this symposium, says: "These three talks show that a County Society and a County Department of Health can pool their knowledge, their thoughtfulness and their energies in harmonious fashion to preserve the health of the citizens of the county at its highest level."

There have been many inquiries, and committees from other Counties in the State have investigated its operation.

The annual meeting of the Third District Branch was well attended. The program has been published in the JOURNAL.

At the annual meeting, Luther C. Payne, M.D., of Liberty, was elected President. On March 16, 1935, Luther C. Payne, M.D., passed to the Great Beyond. Dr. Payne will be greatly missed, both personally and as an efficient and interested officer. Augustus J. Hambrook, M.D., of Troy, who was elected First Vice-President, will officiate as President.

It is sincerely hoped for that more Counties of the Third District may be induced to hold more frequent meetings of their respective County societies.

The report of the Third District Branch cannot be better summarized than in a letter from a secretary of one of its Counties who said of his County: "Better programs, better attendance, closer co-operation, harmony, and peace prevail."

Respectfully submitted,

CLARK G. ROSSMAN, *Councilor*
April 1, 1935

REPORT OF FOURTH DISTRICT BRANCH

To the House of Delegates; Gentlemen:

The work of the Fourth District Branch has continued along the lines of last year, with particular emphasis laid upon need for extension of the post-graduate courses for the Counties, and a better understanding between the County Medical Societies and the County Welfare Officers.

To further the latter object a conference was held last Spring in Elizabethtown which was attended by representatives of all the Counties except one in the District. The President of each County Society, the Chairman of the Economic Committee, and one or two prominent physicians and surgeons from each County were asked to attend. The County Medical Welfare problem was discussed and an effort made to equalize, as far as practicable, the fees charged for indigent cases in the different Counties of the District.

The problem has been taken up by

the different County Societies with the result that all of the Counties of the District except two have some definite understanding with their respective County Welfare Commissioners concerning fees paid for medical services rendered the indigent of the County. Several Counties have a rather complete schedule of such fees while other Counties have more or less of a general understanding with their Welfare Commissioner. Perhaps in none of the Counties is the arrangement all that could be desired, and some are very inadequate, but a good beginning has been made in the direction of relieving the physicians and surgeons of the ever-increasing burden of caring for the indigent. In some of our communities one-third of all hospital patients belong to this class, making the burden an impossible one financially for the profession.

The District Branch meeting was held in September in Gloversville. The Fulton

County Medical Society gave us a wonderful demonstration of hospitality and efficiency. Everything possible was done for the comfort and convenience of their guests.

A program of unusual merit was presented including our State President, Dr. Arthur J. Bedell, Commissioner of Health of New York State, Dr. Thomas Parran, Jr., Dr. Edward M. Livingston of New York City, Dr. Edwin M. Jameson of Saranac Lake, Dr. Wardner D. Ayer of Syracuse, Dr. Richard B. Cattell of the Lahey Clinic, Boston, Dr. William J. Kennedy of Gloversville, and Dr. Herman O. Mosenthal of New York City.

Contrary to some sentiment expressed

at the last State Medical Meeting, the writer feels that the District Branch has a very definite place. He feels however, that the District Branches might function much more efficiently and be of much greater help to the State Society and to the Counties in the District if the President of the State Society could find time at the beginning of each year to coach the District Branch Presidents in the work to be done and to point out special ways in which the District Branch Societies could be of service to the State Society.

Respectfully submitted,

RAYMOND G. PERKINS, *President*

April 1, 1935

REPORT OF FIFTH DISTRICT BRANCH

To the House of Delegates; Gentlemen:

The Annual Meeting of the Fifth District Branch was held in Syracuse on Tuesday, October 2, 1934, with an attendance of more than two hundred and fifty. The meeting was opened with an address of welcome by the President of the Onondaga County Medical Society.

Dr. Bedell, President of the State Society, gave an address in which he drew attention to what the State Society was doing to improve the professional equipment of its members and the application of the TERA to the individual practitioner.

An interesting scientific program followed in which papers were presented by Drs. Frederick H. Flaherty, Leon H. Cornwall, Thomas T. Mackie, Mortimer W. Raynor; Dr. Elliott P. Joslin of Boston spoke on "Pregnancy in Diabetics."

The evening session consisted of a Symposium on the "Importance of Vitamins in Foodstuffs" which was opened with a paper by Dr. Frederick F. Tisdell of Toronto, Canada. The discussion which followed was of great interest as it included the point of view of the dental as well as the medical profession.

The resignation of Dr. William A. Groat as President, in order to render valid his election as Chairman of the Committee on Scientific Work, was accepted with deep regret. The First

Vice-president, Dr. LeRoy F. Hollis, succeeded to the office. The Fifth District Branch is one of the largest branches in area in the State and is composed of the Counties of Herkimer, Jefferson, Lewis, Madison, Onondaga, Oneida, and Oswego.

The County Medical Societies in these different Counties have been holding their regular meetings and have been well attended. Several of the Counties are holding monthly meetings which have created an unusual amount of interest among the physicians.

I was asked by the President to appoint a Committee from the different counties composing the Fifth District Branch to co-operate with the Committees from the other district branches, which I did. It consists of Dr. D. G. Gregor, 500 Woolworth Building, Watertown, from Jefferson County. Dr. S. M. Burns, 31 East 4th St., Oswego, from Oswego County. Dr. Charles D. Post, 608 East Genesee St., Syracuse, from Onondaga County. Dr. F. Edward Jones, Beaver Falls, from Lewis County. Dr. Wm. S. Brady, 1817 Genesee St., Utica, from Oneida County. Dr. Fred C. Sabin, 23 North Ann St., Little Falls, from Herkimer County and Dr. Nelson Brooks, 311 Broad St., Oneida, from Madison County.

Respectfully submitted,

LEROY F. HOLLIS, *President*

April 1, 1935

REPORT OF THE SIXTH DISTRICT BRANCH

To the House of Delegates; Gentlemen:

The Counties comprising this Branch have been active along a number of lines of work. The membership in the County Societies comprising the Sixth District numbers 458. This membership is distributed over a large area, there being nine Counties in this District. They have been active in preventive medicine without exception.

Six out of the nine Counties availed themselves of postgraduate lectures and in only one County did the attendance at these postgraduate lectures fall below 50 per cent. The average attendance computed on membership was 62 per cent. In one County the attendance at the postgraduate lecture actually exceeded the County membership. Although this would not seem adequate in populous districts, when it is recalled that many of the members are obliged to drive many miles, this record is not bad and it seems shows appreciation for what the State Society is attempting to do for them.

Two of the Counties in this District have County Health Units; that of Cortland County has been in existence five years. Two-thirds of our District carry on cancer publicity campaigns. Seven out of the nine have preschool clinics.

Practically all of the Counties have been active in conducting periodic health examinations and all of them have had diphtheria prevention campaigns, some of the Counties not having had diphtheria for two years or more. In the City of Cortland 47 per cent of the preschool children have been immunized against diphtheria. In the County this runs somewhere between 25 and 30 per cent. Among the children who are in school in Cortland County, slightly more than 50 per cent have been immunized.

Three of our County Societies meet monthly, four quarterly, and two semi-annually. It does not seem that quarterly or semi-annual meetings would be satisfactory. It would seem that in order to keep a County organization really alive, they should meet monthly. If it is

claimed that the distance which has to be traveled is too far, this objection could readily be overcome by holding the County meetings at places which would be most accessible to the greatest number in the County.

It would seem also that no County should go without postgraduate lectures. Since one-third of the Counties in our District did not have them, it might be well for them to join with some neighboring County if it is felt that their numbers are too small. Of course, everyone has time to attend medical meetings if they are interested. Furthermore, the question of distance is no longer a valid excuse inasmuch as our County highways are now so vastly improved. The postgraduate lectures which the State Society has made possible have already done much good and are capable of doing a great deal more. More of the Counties should avail themselves of this privilege.

All of the Counties are receiving some pay for the care of indigent cases, but in 90 per cent of our Counties arrangements along this line are still unsatisfactory.

The Counties have been active in support of what they considered sound legislation opposing that which seemed unsound.

The annual meeting of the Branch was held in Cortland, on September 26, 1934. There were present at this meeting 225, representing a fraction less than 50 per cent of the total County memberships in this District. In addition to the President, Dr. Arthur J. Bedell, who addressed the group on the work of the JOURNAL, there were present either as speakers or guests of honor, ex-presidents Dr. Martin B. Tinker, Dr. William D. Johnson, Dr. Frederick H. Flaherty, Dr. Arthur W. Booth, and Dr. Donald Guthrie, President of the Pennsylvania State Medical Society.

Respectfully submitted,

J. E. WATTENBERG, *President*

April 1, 1935

REPORT OF SEVENTH DISTRICT BRANCH

To the House of Delegates; Gentlemen:

The Twenty-Eighth Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York was held on Thursday, September 27, 1934, at the Auburn Country Club in Auburn.

In preparing the program, the question was raised as to whether speakers should be selected from among men of wide reputation or whether an opportunity should be given members of the profession in the District to prepare papers. The wisdom of the Committee's decision for the former plan was justified by a most excellent attendance in spite of the fact that Auburn is in no sense centrally located in the District.

Dr. Arthur J. Bedell, President of the Medical Society of the State of New York, in addressing the District emphasized the importance of each County Society co-operating with the local Welfare Officers in an effort to establish facilities for the medical care of the indigent. He pointed out that no general plan had been formulated and, conse-

quently, each Society must adopt the plan best suited for its local needs.

Dr. Russell L. Cecil gave a most interesting summary of the modern conception of arthritis with special emphasis on treatment.

Dr. Harrison S. Martland talked on Common and Unusual Heart Lesions, illustrating his remarks with interesting lantern slides.

After luncheon, Dr. Frank Lahey addressed the District Branch on the Management of Gastric Lesions, Peptic Ulcer, and Malignancy. Dr. Lahey's remarks were expressed in his usual clear and logical manner which makes his talks so interesting and practical for the general practitioner as well as the surgeon.

Dr. Foster Kennedy changed the subject of his address from Recent Advances in Neurology to Epilepsy. He presented a new and most interesting conception of epilepsy.

Limited time made it impossible to open these papers for general discussion.

Respectfully submitted,

ALFRED K. BATES, *President*

REPORT OF EIGHTH DISTRICT BRANCH

To the House of Delegates; Gentlemen:

Following a Spring conference between the Executive Officer and representatives of component Counties, Jamestown was selected for the 1934 annual meeting which was held in October. Dr. Malcolm H. V. Cameron, president of the Toronto Academy of Medicine, presented the program feature on the topic of gallbladder disease. Dr. Wallace B. Hamby with the aid of unusual slides brought the subject of neurosurgery up to date. Dr. Joseph S. Lawrence expounded the public welfare law. Complaint was registered by members that no opportunity was afforded for the discussion of medical relief at this meeting. Niagara County sent resolutions requesting the TERA to lay down rules and regulations requiring welfare departments to designate the family physician or physician-of-choice instead of part-time political appointees to care for the indigent sick; but the length of the program prevented consideration of this subject. This was unfortunate because of a feeling in many quarters that leav-

ing such matters for negotiation between local County societies and local welfare commissioners had proven a dismal failure in the more populous centers. Whereas promulgation of such a requirement by a central authority such as the Director of the TERA as a condition of the TERA approving refund to the cities by the State and Federal government would immediately accomplish what local negotiation has failed to accomplish in the five years the new public welfare law has been effective.

One regular meeting of the Council was attended. At the close of the year 1934 the officers and committees of the State Society were assembled to co-relate activities.

During the early months of 1935, Niagara County provided funds for supporting activity in favor of the enactment of a medical-lien law in this State. Meetings of the Counties of Erie and Orleans were attended with excellent co-operation from each.

Respectfully submitted,

R. H. SHERWOOD, *President*

MEDICAL SOCIETY OF THE STATE OF NEW YORK

ANNUAL MEETING, ALBANY, MAY 13, 14, 15

House of Delegates

The regular Annual Meeting of the House of Delegates of the Medical Society of the State of New York will be called to order at 10:00 A.M., Daylight Saving Time, on Monday, May 13, 1935, in the Hotel Ten Eyck.

SAMUEL J. KOPETZKY, *Speaker*
DANIEL S. DOUGHERTY, *Secretary*

Annual Meeting

The Annual Meeting of the Medical Society of the State of New York will be held on Tuesday, May 14, 1935, at 7:00 P.M. in the Hotel Ten Eyck.

ARTHUR J. BEDELL, *President*
DANIEL S. DOUGHERTY, *Secretary*

Registration

The Hotel Ten Eyck will be the general headquarters. Registration for Delegates will be held on Monday morning, May 13, from 9:00 o'clock; for members on Monday, Tuesday, and Wednesday, May 13, 14, 15, from 9:00 A.M. to 6:00 P.M.

Exhibits

Scientific and Technical Exhibits will be located in the Hotel Ten Eyck.

Scientific Sessions

General Sessions on Tuesday and Wednesday afternoons. Section meetings on Tuesday and Wednesday mornings will be held in the State Capitol.

129th Annual Meeting

Calling the Society to order by the President, Arthur J. Bedell, M.D.

Reading of the minutes of the 128th Annual Meeting by the Secretary, Daniel S. Dougherty, M.D.

Address of Welcome by the Chairman of the Committee on Arrangements, Frederic C. Conway, M.D.

Address of Welcome by the Hon. John Boyd Thacher, Mayor of the City of Albany.

President's address, Arthur J. Bedell, M.D.

Introduction of the President-elect, Frederic E. Sondern, M.D.

The Annual Banquet

The Annual Banquet will be held in the Hotel Ten Eyck, Tuesday, May 14, 1935, at 7:00 P.M. The guests of honor will include the Honorable Herbert H. Lehman, Governor of the State of New York, the President and Secretary of the American Medical Association, and the Presidents of the adjoining State Societies.

Requests for tickets and reservations for tables should be sent to Dr. Edgar A. VanderVeer, Secretary of the Dinner Committee, 28 Eagle Street, Albany. Tickets will be \$3.00.

Delegates Dinner

Dinner for the Delegates will be served in the Hotel Ten Eyck on Monday following the adjournment of the afternoon session of the House of Delegates. Tickets can be procured from the Secretary of the Medical Society of the State of New York, Dr. Daniel S. Dougherty, 2 East 103rd Street, New York City.

Ladies Auxiliary

Special entertainment will be given to the ladies under the auspices of the Ladies Auxiliary of the Medical Society of the County of Albany.

Hotels

A list of the hotels will be found in the JOURNAL and members are advised to make their reservations in advance of the meeting so they will be able to secure the desired accommodations.

Validation of Railroad Tickets

Members holding railroad certificates entitling them to a reduction in return railroad fare must have them signed and validated at the Society's Registration Desk before purchasing tickets for the return trip at the special fare allowed to those attending the meeting.

Scientific Program

All Meetings Will Be Held By Daylight Saving Time

GENERAL SESSIONS

PLACE OF MEETING—STATE CAPITOL, ASSEMBLY CHAMBER

Tuesday, May 14—2:00 p.m.

1. "The Function of the American Medical Association," Walter L. Biering, M.D., President of the American Medical Association, Des Moines, Iowa (invited guest).

2. "Medicine of Today," Olin West, M.D., Secretary and General Manager of the American Medical Association, Chicago, Ill. (invited guest).

3. "Recent Advances in Pathology of the Cardiovascular System," Harrison S. Martland, M.D., Newark, N. J. (invited guest).

Wednesday, May 15—2:00 p.m.

1. "The Treatment of Pneumonia," Arthur F. Chace, M.D., New York.

2. "The Problem of the Broken Hip," John J. Moorhead, M.D., New York.

3. "Facts Concerning the Treatment of Anemia," William P. Murphy, M.D., Boston, Mass. (invited guest).

4. "Hints for Recognizing the Patient who will Probably not be Helped by an Abdominal Operation." Walter C. Alvarez, M.D., Rochester, Minn. (invited guest).

5. "Face Pain," George H. Hyslop, M.D., New York.

THE SECTIONS

[All papers read before the Society by members become the property of the Society. The original copy of each paper shall be left with the Secretary of the Section. Discussers should have their remarks typed and hand them to the Secretary if they wish them published. Section meetings shall begin promptly at the hour specified.]

SECTION ON MEDICINE

Chairman, FRANK BETHEL CROSS, M.D., Brooklyn; Secretary, JOHN S. LAWRENCE, M.D., Rochester; Place of Meeting, State Capitol, Assembly Chamber

Tuesday, May 14—10:00 a.m.

1. "Clinical and Laboratory Aspects of Bacteriemia," George M. Mackenzie, M.D., Cooperstown, and R. M. Pike, Ph.D., Cooperstown (invited guest). Discussion opened by Ruth Gilbert, M.D., Albany, and Oliver W. H. Mitchell, M.D., Syracuse.

2. "Primary Carcinoma of the Lung," Lewis F. Frissell, M.D., New York. Discussion opened by Henry M. Moses, M.D., Brooklyn, Leila C. Knox, M.D., New York, and Byron Stookey, M.D., New York.

3. "The Application of Diagnostic Criteria to the Treatment of the Anemias," Frank H. Bethell, M.D., Ann Arbor, Mich. (invited guest). Discussion opened by William P. Murphy, M.D., Boston, Mass. (invited guest), Ellery G. Allen, M.D., Syracuse, and L. Whittington Gorham, M.D., Albany.

4. "The Treatment of Gastroduodenal Ulcers as an Office Procedure," Anthony Bassler, M.D., New York. Discussion opened by Harry L. Segal, M.D., Rochester, and I. Harris Levy, M.D., Syracuse.

Wednesday, May 15—9:00 a.m.

1. "Why Vaccines Fail," C. Ward Crampton, M.D., New York. Discussion opened by Charles H. Hitchcock, M.D., Syracuse.

2. "A Critical Study of the Value of a 'Cure Regime' in the Treatment of Coronary Disease," Carl R. Comstock, M.D., Saratoga Springs. Discussion opened by Walter S. McClellan, M.D., Saratoga Springs, and L. Whittington Gorham, M.D., Albany.

3. "The Diagnostic Significance of Gallop Rhythm," C. Saul Danzer, M.D., Brooklyn. Discussion opened by William

D. Stroud, M.D., Philadelphia, Pa. (invited guest) and Edwin P. Maynard, Jr., M.D., Brooklyn.

4. "An Appraisal of Induced Pneumothorax in the Lobar Pneumonias," Jesse G. M. Bullowa, M.D., New York.

Discussion opened by Edward C. Reifenschein, M.D., Syracuse, Edgar Mayer, M.D., New York, James B. Amberson, Jr., New York, Milton B. Rosenblüth, M.D., New York, Joseph R. Wiseman, M.D., Syracuse.

SECTION ON SURGERY

Chairman, EDGAR A. VANDER VEER, M.D., Albany; *Secretary*, JOHN C. BRADY, M.D., Buffalo; *Place of Meeting*, State Capitol, Assembly Parlor

Tuesday, May 14—10:00 a.m.

1. "The Association of Fractures and Paget's Disease. (Osteitis Deformans)," Clarence A. Traver, M.D., Albany. Discussion opened by William P. Howard, M.D., Albany.

2. "The Mikulicz as Opposed to the One Stage Operation for Carcinoma of the Colon," C. V. Burt, M.D., New York. Discussion opened by Chas. Gordon Heyd, M.D., New York.

3. "Principles Underlying Surgery for Cancer of the Face," Herbert Willy Meyer, M.D., New York. Discussion opened by William J. Hoffman, M.D., New York.

Wednesday, May 15—9:30 a.m.

SYMPOSIUM: "Surgery of the Chest"

1. "Surgical Treatment of Empyema," Howard Lilienthal, M.D., New York.

2. "Intrapulmonary Suppuration and Cancer of the Lung," Carl Eggers, M.D., New York.

3. "The Surgical Treatment of Anterior and Posterior Mediastinal Tumors," Stuart W. Harrington, M.D., Mayo Clinic, Rochester, Minn. (invited guest).

4. "The Surgical Treatment of Pulmonary Tuberculosis," Frank B. Berry, M.D., New York.

Discussion opened by Edgar W. Phillips, M.D., Rochester, and Donald R. McKay, M.D., Buffalo.

SECTION ON OBSTETRICS AND GYNECOLOGY

Chairman, HOWARD C. TAYLOR, JR., M.D., New York; *Secretary*, CHARLES J. MARSHALL, M. D., Binghamton; *Place of Meeting*, State Capitol, Room 332

Tuesday, May 14—10:00 a.m.

1. "The Treatment of Placenta Praevia by Conservative Measures," Ward L. Ekas, M.D., Rochester. Discussion by James K. Quigley, M.D., Rochester.

2. "The Pathology of the Fatal Injuries to the Newborn," William E. Studdiford, M.D., New York. Discussion opened by Frederick A. Hemsath, M.D., New York.

3. "Laboratory Aids in the Diagnosis and Treatment of Pelvic Infections," Thomas C. Peightal, M.D., New York. Discussion opened by Victor W. Bergstrom, M.D., Binghamton.

4. "The Relief of Intractable Cases of Dysmenorrhea by Pelvic Sympathectomy," Frederick S. Wetherell, M.D., Syracuse. Discussion opened by Thomas P. Farmer, M.D., Syracuse.

Wednesday, May 15—9:00 a.m.

1. "The Prognosis of Cancer of the Cervix Treated by Irradiation," Nelson B. Sackett, M.D., New York. Discussion opened by Ira I. Kaplan, M.D., New York.

2. "The Symphysis Pubis and Its Relation to Backache," Milton G. Potter, M.D., Buffalo. Discussion opened by John M. Barnes, M.D., Buffalo.

3. "Types of Pelves Commonly Found in Obvious Endocrine Disturbances," William E. Caldwell, M.D., New York. Discussion opened by D. Anthony D'Esopo, M.D., New York.

4. "The Recurrence of Toxemia of Pregnancy," Alvin J. B. Tillman, M.D., New York. Discussion opened by Edward C. Hughes, M.D., Syracuse.

SECTION ON NEUROLOGY AND PSYCHIATRY

Chairman, JOHN L. ECKEL, M.D., Buffalo; *Secretary*, BYRON STOOKEY, M.D., New York; *Place of Meeting*, State Capitol, Room 424

Tuesday, May 14—10:00 a.m.

1. "A Clinical and Pathologic Study of Alcoholism," Lloyd H. Ziegler, M.D., Albany, and Henrietta C. Horner, M.D., Albany. Discussion opened by Victor C. Jacobsen, M.D., Albany, and John L. Eckel, M.D., Buffalo.

2. "Acoustic Neurinomas in the Stage of Normal Intracranial Pressure," Wallace B. Hamby, M.D., Buffalo. Discussion opened by Byron Stookey, M.D., New York.

3. "Tumors of the Base of the Skull," S. Bernard Wortis, M.D., New York, and Samuel Brock, M.D., New York. Discussion opened by John L. Eckel, M.D., Buffalo, and Lloyd H. Ziegler, M.D., Albany.

4. "A Study of Early Developing Schizophrenia," Eric Kent Clarke, M.D., Rochester, and Daniel B. Peeler, M.D., Rochester. Discussion opened by Lloyd H. Ziegler, M.D., Albany.

5. "A Case of Myasthenia Gravis with Pathological Changes in the Central Nervous System," Charles A. McKendree, M.D., New York, and Abner Wolf, M.D., New York. Discussion opened by Albert G. Odell, M.D., Clifton Springs.

Wednesday, May 15—9:00 a.m.

1. Chairman's Address: "The Place of Neuropsychiatry in a General Hospital," John L. Eckel, M.D., Buffalo.

2. "The Value of the Erythrocyte Sedimentation Rate Determination in Psychiatric Cases," Hugh S. Gregory, M.D., Binghamton. Discussion opened by George C. Bower, M.D., Marcy.

3. "Intracranial Hemorrhage, Its Anatomical Forms and Differential Diagnosis," Joseph H. Globus, M.D., New York. Discussion opened by Aramando Ferraro, M.D., New York.

4. "Acute Encephalomyelitis and Its Relationship to Multiple and Diffuse Sclerosis," Aramando Ferraro, M.D., New York and G. A. Jervis, M.D., New York (invited guest). Discussion opened by Joseph H. Globus, M.D., New York.

5. "Purpura Hemorrhagica with Intracranial Hemorrhage," Paul H. Garvey, M.D., Rochester, and Doran J. Stephens, M.D., Rochester. Discussion opened by Walter O. Klingman, M.D., New York.

6. "Observations on Treatment of Mental Disorders in Small Groups," Eugene N. Boudreau, M.D., Syracuse. Discussion opened by Hugh S. Gregory, M.D., Binghamton.

SECTION ON PEDIATRICS

Chairman, GEORGE C. SINCERBEAUX, M.D., Auburn; *Vice-Chairman*, GEORGE M. RETAN, M.D., Syracuse; *Secretary*, JOHN DORSEY CRAIG, M.D., New York; *Place of Meeting*, State Capitol, Room 342

Tuesday, May 14—10:00 a.m.

1. "Peptic Ulcer in Childhood with Case Reports," Frank J. Williams, M.D., Albany. Discussion opened by Arthur W. Benson, M.D., Troy.

2. "Infant Feeding; Historical Background and Modern Practice," Grover F. Powers, M.D., New Haven, Conn. (invited guest). Discussion opened by Henry L. K. Shaw, M.D., Albany.

3. "A Study of Infant Care in a Rural Community," Marjorie F. Murray, M.D., Cooperstown. Discussion opened by George M. Retan, M.D., Syracuse.

4. "Clinical Results of Anterior Pituitary Therapy in Children," with

Lantern Slide Demonstration, A. Wilnot Jacobsen, M.D., Buffalo. Discussion opened by Murray B. Gordon, M.D., Brooklyn.

Wednesday, May 15—9:00 a.m.

1. "Nephritis in Childhood," Marshall C. Pease, M.D., New York. Discussion opened by Adolph G. DeSanctis, M.D., New York.

2. "Whooping Cough Vaccine as an Immunizing Agent," Louis W. Sauer, M.D., Evanston, Ill. (invited guest). Discussion opened by John Dorsey Craig, M.D., New York.

3. "Whole Blood in the Treatment of

Whooping Cough," William L. Bradford, M.D., Rochester. Discussion opened by John Dorsey Craig, M.D., New York.

4. "Sickle Cell Anemia in a Child of Italian Parentage," Carl Laws, M.D.,

Brooklyn. Discussion opened by Brewster C. Doust, M.D., Syracuse.

5. "The Work of the Joint Subcommittee on the Deaf and Hard of Hearing," Fairfax Hall, M.D., New Rochelle.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Chairman, GEORGE M. MACKEE, M.D., New York; *Secretary*, LOPO DE MELLO, M.D., Syracuse; *Place of Meeting*, State Capitol, Room 441

Tuesday, May 14—10:00 a.m.

1. "Removal of Nonmalignant Moles, with Final Cosmetic Results," Robert R. M. McLaughlin, M.D., New York. Discussion opened by Harry D. Parkhurst, M.D., Utica.

2. "Sensitivity to Soap Solutions," James W. Jordan, M.D., Buffalo and Earl D. Osborne, M.D., Buffalo. Discussion by John H. Hunt, M.D., Elmira.

3. "The Practical Management of Dermatitis with an Allergic Etiology," Herbert H. Bauckus, M.D., Buffalo. Discussion opened by Leon H. Griggs, M.D., Syracuse.

4. "Burning Tongue," Howard Fox, M.D., New York. Discussion opened by Anthony C. Cipollaro, M.D., New York.

5. "Treatment of Cardiovascular Syphilis," Joseph E. Moore, M.D., Baltimore, Md. (invited guest).

Wednesday, May 15—9:00 a.m.

1. "Lipoidosis Cutis et Mucosae,"

Ralph N. Tripp, M.D., New York. Discussion opened by Paul E. Bechet, M.D., New York.

2. "Tuberculous and Tuberculoid Skin Diseases," Timothy J. Riordan, M.D., New York. Discussion opened by J. Frank Fraser, M.D., New York.

3. "The Field of Dermatology," William Allen Pusey, M.D., Chicago, Ill. (invited guest).

4. "Nails and Their Diseases," Mortimer J. Cantor, M.D., Brooklyn. Discussion opened by Clarence H. Peachey, M.D., Rochester.

5. "The Sources and Symptoms of Arsenical Poisoning from the Standpoint of the Dermatologist," A. Benson Cannon, M.D., New York. Discussion opened by John R. Schermerhorn, M.D., Schenectady.

6. "Cutaneous Calcinosis," Maurice J. Costello, M.D., New York. Discussion opened by Edward R. Maloney, M.D., New York.

SECTION ON OPHTHALMOLOGY AND OTOLARYNGOLOGY

Chairman, WEBB W. WEEKS, M.D., New York; *Secretary*, JOHN F. FAIRBAIRN, M.D., Buffalo; *Place of Meeting*, State Capitol, Senate Chamber

Tuesday, May 14—9:00 a.m.

Instructional Hour 9:00 A.M. to 10:00 A.M.: "A Study of the Pathology in Cases of Sympathetic Ophthalmia," Bernard Samuels, M.D., New York.

1. "Treatment of Sympathetic Ophthalmia with Antidiphtheric Serum," Frederick H. Verhoeff, M.D., Boston, Mass. (invited guest). Discussion opened by Ben Witt Key, M.D., New York.

2. "Allergy in Its Relation to Sympathetic Ophthalmia," Alan C. Woods, M.D., Baltimore, Md. (invited guest). Discussion by Conrad Berens, M.D., N.Y.

3. "Surgical Treatment of Sympathetic Ophthalmia and Its Complications," John F. Gipner, M.D., Rochester.

4. "A Survey of Cases of Sympathetic

Ophthalmia Occurring in New York State," Harold H. Joy, M.D., Syracuse.

5. "Treatment of Blood Stream Infections with Gold Sodium Chloride," Ivan J. Koenig, M.D., Buffalo.

Wednesday, May 15—9:00 a.m.

Instructional Hour 9 A.M. to 10:00 A.M.: (a) "Anatomy of the Temporal Bone," (b) "Anatomy of the Nasal Sinuses," Edgar Burchell, B.Sc., New York (invited guest).

1. "The Diagnosis of Deafness Based Upon Functional Testing," Clayton M. Brown, M.D., Buffalo. Discussion opened by Chester C. Cott, M.D., Buffalo.

2. "Treatment of Hay Fever and Hyperesthetic Rhinitis by Ionization," Lee M. Hurd, M.D., New York. Dis-

cussion opened by Claude G. Crane, M.D., Brooklyn.

3. "Experimental Findings in Petrisitis," (a) Historical data, Joseph G. Druss, M.D., New York; (b) Pathological find-

ings, Harry Rosenwasser, M.D., New York; (c) Experimental work, Samuel Rosen, M.D., New York. Discussion opened by Isidore Friesner, M.D., New York.

SECTION ON PUBLIC HEALTH, HYGIENE AND SANITATION

Chairman, WALTER A. LEONARD, M.D., Cambridge; *Secretary*, JOHN A. CONWAY, M.D., Hornell; *Place of Meeting*, State Capitol, Room 409

Tuesday, May 14—10:00 a.m.

1. "The New State Tuberculosis Hospitals," Robert E. Plunkett, M.D., Albany. Discussion opened by H. St. John Williams, M.D., Poughkeepsie.

2. "Practical Suggestions for Community Health Education," Gilbert deL. Forbes, M.D., Kendall. Discussion opened by Leo F. Schiff, M.D., Plattsburg.

3. "The Administrative Aspects of Vitamin D Milk Control," Paul B. Brooks, M.D., Albany. Discussion opened by James A. Tobey, D.P.H., New York (invited guest).

4. "Diphtheria Epidemic in a Hospital," James E. Perkins, M.D., Albany. Discussion opened by Frank E. Coughlin, M.D., Albany.

Wednesday, May 15—9:00 a.m.

1. "The Use of Immune Blood in the Prophylaxis of Measles and Whooping Cough," William L. Bradford, M.D., Rochester.

2. "Measles Prophylaxis," Samuel Karelitz, M.D., New York. Discussion opened by Bela Schick, M.D., New-York, and George R. Murphy, M.D., Elmira.

SYMPOSIUM: "Poliomyelitis"

3. "Symptomatology and Treatment of Acute Poliomyelitis," Josephine B. Neal, M.D., New York.

4. "Active Immunization against Poliomyelitis," Maurice Brodie, M.D., New York (invited guest).

5. "General Discussion of Poliomyelitis," William H. Park, M.D., New York. Discussion, G. H. Ramsey, M.D., Albany.

SECTION ON UROLOGY

Chairman, THOMAS F. LAURIE, M.D., Syracuse; *Secretary*, ERNEST M. WATSON, M.D., Buffalo; *Place of Meeting*, State Capitol, Room 437

Tuesday, May 14—10:00 a.m.

1. "Bacteriemia Following Instrumentation of the Infected Urinary Tract," John H. Powers, M.D., Cooperstown. Discussion opened by James H. Borrell, M.D., Buffalo.

2. "Elusive Ulcer of the Bladder with Special Reference to the Use of Phenol," Nathan P. Sears, M.D., Syracuse. Discussion opened by H. Dawson Furniss, M.D., New York.

3. "Modern Renal Surgery," Oswald S. Lowsley, M.D., New York. Discussion opened by Winfield W. Scott, M.D., Rochester.

Wednesday, May 15—9:00 a.m.

1. "The Present Status of the Prostatic Problem," Henry G. Bugbee, M.D., New York. Discussion opened by Arthur H. Paine, M.D., Rochester.

2. "X-ray and Radium Therapy in Diseases of the Genito-Urinary System," George G. Smith, M.D., Boston, Mass. (invited guest). Discussion opened by Benjamin S. Barringer, M.D., New York.

3. "Calculus in the Upper Urinary Tract," Alexander Randall, M.D., Philadelphia, Pa. (invited guest). Discussion opened by Nathaniel P. Rathbun, M.D., Brooklyn.

SECTION ON RADIOLOGY

Chairman, DONALD S. CHILDS, M.D., Syracuse; *Vice Chairman*, LEO P. LARKIN, Ithaca; *Secretary*, JAMES M. FLYNN, M.D., Rochester; *Place of Meeting*, State Capitol, Room 442

Tuesday, May 14—10:00 a.m.

1. "A Study of the End Results in the

Treatment of Cancer Patients with a Report of Approximately 400 Autopsies,"

Ira I. Kaplan, M.D., New York. Discussion opened by Angelo M. Sala, M.D., New York.

2. "Trichobezoar" (Hair-cast of Stomach), Carlton F. Potter, M.D., Syracuse.

3. "The Review of Five Thousand Gastrointestinal X-ray Examinations with a Summary of the Conclusions," Edward C. Koenig, M.D., Buffalo. Discussion opened by Leo P. Larkin, M.D., Ithaca.

4. "X-ray Therapy in Upper Respiratory Infections," Alfred L. L. Bell, M.D., Brooklyn.

5. "Pulmonary Tuberculosis; Serial Roentgen Studies in Superinfections," Henry K. Taylor, M.D., New York. Discussion opened by George G. Ornstein, New York.

Wednesday, May 15—9:00 a.m.

1. "Pneumoconiosis; A Study of Some Five Hundred Cases," Clifford R. Orr, M.D., Buffalo. Discussion opened by Donald R. McKay, M.D., Buffalo.

2. "Radium Therapy," Douglas Quick, M.B., New York. Discussion opened by Burton T. Simpson, M.D., Buffalo.

3. "The Use of the Roentgen Ray in the Early Diagnosis of Infections Caused by Gas Forming Organisms," Leslie R. Lingeman, M.D., Rochester. Discussion opened by Max A. Almy, M.D., Rochester.

4. "The Relationship of Certain Technical Factors in the Roentgenological Examination of the Lungs," Charles C. McCoy, M.D., Cooperstown.

Scientific Exhibit

Hotel Ten Eyck, Mezzanine

Dr. Russell L. Cecil, New York (1. Committee on Public Health and Medical Education, Medical Society of the State of New York; 2. New York State Department of Health; 3. Metropolitan Life Insurance Co.): "*Exhibit on Pneumonia.*"

Description: Charts illustrating: (1) Incidence and death rate of pneumonia in various countries; (2) Incidence and mortality for various types of pneumonia; (3) Results of serum treatment in various types; (4) Demonstration of various typing methods; (5) Motion picture demonstration by Dr. Jesse Bullowa, "The Management of Pneumonia."

Dr. Jesse G. M. Bullowa, Littauer Pneumonia Research Fund of New York University, New York: "*Management of Pneumonia.*"

Description: Three charts showing typing methods, etc. Pneumothorax statistics. Neufeld typing demonstration. Film by Dr. M. B. Ferderber.

Dr. John C. A. Gerster, New York City Cancer Committee (American Society for the Control of Cancer), New York: "*Health's Highways*"

Description: A series of charts, comprising photographs, drawings and text,

designed to show the accomplishments in medical research, from earliest times, with especial reference to advances in cancer therapy. Particular stress is laid on those achievements which have been the result of animal experimentation.

Dr. Irving Gray, Brooklyn: "*Treatment of Lead Poisoning*"

Description: Measures in the therapeutic and dietetic management of patients ill with acute, subacute, and chronic lead poisoning will be displayed. Procedures in the treatment will be outlined.

Dr. J. Thompson Stevens, New York: "*Result of Radiotherapy and Electrosurgery in Accessible Malignancies*"

Description: Photographs before and after treatment in accessible malignancies, cases which were alive and free from malignant disease for five years and longer.

Drs. Jane Sands Robb, J. G. Fred Hiss, and Robert Robb, Syracuse University: "*Further Studies on Coronary Distribution in Human Hearts*"

Description: Dissections of injected human hearts have been made to demonstrate the muscular architecture of the ventricles and the blood supply to these

muscles. Electrocardiograms showing the application of this data to studies in condition are at hand.

Dr. G. Allen Robinson, New York: *"The Radium Treatment of Hemangiomas"*

Description: Classification of types of vascular tumors occurring in children. Dosage and technic of radium application. Results obtained in a large series of cases will be shown.

Dr. Wardner D. Ayer, Syracuse University: *"The Aneurysm of the Circle of Willis and Spontaneous Subarachnoid Hemorrhage"*

Description: Twenty photographs with epitomized histories.

Dr. Lee A. Hadley, Syracuse University: *"Apophyseal Subluxation; Disturbances in and about the Intervertebral Foramen Causing Back Pain"*

Description: Conditions causing both local and referred pain are illustrated by anatomical specimens, microscopic sections and x-ray films.

Dr. Frederick S. Wetherell, Syracuse University: *"Surgery of the Sympathetic Nervous System; Its Application to Various 'Medical' Conditions"*

Description: A number of anatomical dissections of various ganglionated trunks and plexuses will be shown. Case histories of patients on whom various sympathetic nerve operations have been performed will be shown on placards. A moving picture of the operation for removal of the superior hypogastric plexus (presacral nerve), as applied for the relief of pelvic pain, will be projected.

New York State Medical Library, Albany: *"New York State Medical Library"*

Description: Posters. Also the New York State Medical Library cordially urges all of the members of the Medical Society of the State of New York to visit their library in the Education Building. There are over 40,000 volumes in the Medical Library and over 500 periodicals are received currently. Special

books are sent to the borrower on request or selected material will be sent if the subject desired is given. This service is extended, without charge, to physicians and nurses registered in New York State. The only obligation imposed on the borrower is the payment of the transportation charges both ways.

Dr. Burton T. Simpson, State Institute for the Study of Malignant Diseases, Buffalo: *"Cancer"*

Description: Transparencies illustrating cases of cancer which have been cured. Models showing the pumping of radon, the radium pack, x-ray machine, and surgery.

Dr. Arthur J. Bedell, Albany: *"Modern Photography of the Eyes"*

Description: The group will include photographs of the face showing gross ocular anomalies, stereoscopic pictures of the external diseases, photographs of cataracts, natural color photographs and stereoscopic fundus photographs dealing especially with the local manifestations of systemic disorders, nephritis, hypertension, diabetes, syphilis, tuberculosis, and brain tumors.

Drs. Bernard Samuels and E. B. Burchell, New York Eye & Ear Infirmary, New York: *"Anatomical Preparations of Eye and Ear; Rare Old Books"*

Description: (1) Eye preparations of macroscopic mounts demonstrating all the familiar eye lesions, including retinitis pigmentosa and neoplasms; (2) Temporal bone, numerous dissections; (3) Early editions, mostly of English and American textbooks.

Drs. Eilif C. Hanssen, Hubbard Lynch, and Charlotte H. Phillips, New York Post-Graduate Medical School and Hospital, New York: *"Diagnosis of Disease of the Gall Bladder"*

Description: Panels showing statistical studies of a control series of 99 patients, compared with groups of medical and surgical cases, each studied by history, chemical blood tests, cholecysto-

grams and biliary tract drainage. Dry model of stomach and biliary tract showing duodenal tube in place. Pathological specimens of gall bladder. Typical illuminated cholecystograms. Complete equipment for biliary tract drainage.

Drs. Albert Pfeiffer, Rudolph Ruedemann, Jr., Thomas F. Laurie, and Kenneth M. Davenport, New York State Department of Health, Albany: *"Clinical Manifestations of Syphilis"*

Description: Strip films and moulages showing lesions of syphilis and allied conditions for purposes of differential diagnosis. Demonstration of the capillary tube outfit for dark field examination of spirocheta pallida.

Drs. Augustus J. Hambrook and Fairfax Hall, Committee on the Deaf and Hard of Hearing, Sub-committee of Committee on Public Health and Public Relations of Medical Society of the State of New York: *"The Hard of Hearing"*

Description: Signs and Panels. Audiometers.

Dr. Samuel Weiss, New York Poly-clinic Medical School and Hospital, New York: *"Gastroenterology; Graduate and Postgraduate Teaching"*

Description: Models, charts and roentgen ray films of normal and pathological gastrointestinal conditions. Apparatus and chemicals for diagnosis and treatment of diseases of the digestive system, including liver, gallbladder and pancreas. Gastroscopy with flexible gastroscope and gastric photography.

Dr. Jacques W. Maliniak, New York: *"Variety in Plastic and Reconstructive Surgery"*

Description: Plastic repair of a variety of congenital and acquired deformities of the face and form is illustrated by means of charts, photographs and casts. The pre- and postoperative results and the surgical technic for some deformities is shown in a motion picture. Special emphasis is placed on the repair in various stages of extensive post-traumatic deformities about the facial cavities. The

importance of functional as well as cosmetic restoration is stressed. Repair in the following deformities will be presented: partial and total rhinoplasty; partial loss of lip; defects of cheek caused by radium burns; secondary cleft lip nose; burn of neck, buttocks and chest; repair of conspicuously enlarged breast hypertrophy.

Dr. William E. Caldwell, Department of Obstetrics and Gynecology, Columbia University and the Sloane Hospital for Women with the assistance of the Roentgen Ray Department of the Presbyterian Hospital, New York: *"Types of Pelves Commonly Found in Obvious Endocrine Disturbances"*

Description: The exhibit will include a minimum of fifteen framed illustrations of the different types of pelves, along with a number of mounted specimens. Case studies of the pelvic shape in primary amenorrhea and other endocrine conditions will be shown by means of roentgenograms, suitably labeled. The x-ray technic used for pelvic studies will also be diagrammatically illustrated.

Division of Laboratories and Research, New York State Department of Health, Albany: *"Laboratory Aids in Diagnosis"*

Description: Data relative to amebiasis. Pneumococcus type differentiation. Collection of duodenal contents. Collection and examination of chancre fluid. Tissue diagnosis (biopsy material). Various diagnostic procedures.

Dr. Albert S. Hyman, Witkin Foundation for the Study and Prevention of Heart Disease, New York: *"Infra-red Photography in the Study of Cardio-vascular Disease"*

Description: Original photographs, charts, diagrams and models illustrating the selective possibilities of infra-red photography in the studies and examination of the superficial blood vessels of the skin. Changes in venous pressure seen in early stages of valvular heart disease may be estimated by infra-red radiation and specialized photography; these changes precede the usual clinical signs

of congestive failure and are of considerable prognostic significance.

Drs. Albert S. Hyman, J. Sante Diasio, and Morris Zimmerman, Witkin Foundation for the Study and Prevention of Heart Disease, New York: "*Trans-Thoracic Electrocardiography*"

Description: Demonstration of the 9-lead hook up. Electrocardiograms made by the conventional three lead method frequently (about 22 per cent) fail to reveal widespread coronary arterial pathology with its associated heart muscle damage. The theory of "silent areas" in the heart is based upon the incomplete expression of the electrophysiology of the Einthoven triangle. The adoption of the cone theory permits three dimensional study of cardiac electrodynamics. The use of the trans-thoracic leads is shown by original diagrams, plates, photographs, models, and electrocardiograms.

Drs. Henry K. Taylor, Solomon Schwartz, and Oscar Auerbach, Seaview Hospital, New York: "*Pulmonary Tuberculosis*"

Description: The exhibit illustrates all types of superinfections and demonstrates the roentgenological application of a clinical classification, where all types are divided into a benign and malignant group. The benign group requires no surgical collapse or therapy measures. The malignant group is the only group where collapse therapy measures are indicated. The roentgen appearance of the chest following the various surgical pro-

cedures are demonstrated. Included are Pneumothorax, unilateral and bilateral; Pneumoclysis, closed; Phrenicectomy; Apicolysis with plombs; Caspar operation; Paravertebral thoracoplasties, all stages; Bilateral upper stage thoracoplasty. Also roentgenograms of sixty cases with deposits in pneumothorax cavities. Mounted pathological specimens to demonstrate practically all lesions visible in roentgenograms.

American Medical Association, Chicago, Ill.: "*Cutaneous Granulomas*"

Description: A collection of about 150 photographs showing cutaneous granulomas which the physician may encounter in general practice.

Dr. Anna Furedi, New York Institute of Clinical and Oral Pathology, Inc., New York: "*Tumors of the Oral Cavity*"

Description: Clinical photographs, x-rays, and microphotographs of cases illustrating the importance of the correlations of clinical findings; x-ray examination and histopathological evidence.

Dr. Simon L. Ruskin, Bronx Hospital, New York: "(1) *Histopathology of Atrophic Rhinitis and Ozena*; (2) *Technic of Blocking the Sphenopalatine Ganglion*"

Description: (1) Transparencies illustrating differential diagnosis histopathologically between atrophic rhinitis and ozena. (2) Transparencies showing anatomy and technic of blocking the sphenopalatine ganglion.

Technical Exhibit

HOTEL TEN EYCK

Albany Surgical Co., Inc., of Albany (members NRA) (Booth 19). This company desires to function with and for the best interests of the medical profession in its effort to serve mankind in proficient and ethical accord. The Albany Surgical Staff and officers heartily welcome members of the Society to visit our store while they are in Albany.

Warren E. Collins, Inc., Boston, Mass. (Booth 6), "Pioneers of Respiration Apparatus," will show the very latest, up-to-date equipment—for the administration of prolonged artificial respiration—for efficient, effective oxygen therapy and simple, accurate metabolic determinations. Demonstrations gladly given.

Coward Shoe, New York City (Booth 18). On display at the Coward booth are many interesting plaster casts of deformed feet. Motion pictures show vividly the foot in action and its requirements for walking . . . also how shoes can be intelligently applied for absolute comfort. Over a 70-year period Coward has contacted practically every form of foot disorder. The result is shown in 79 different lasts for as many differently shaped feet.

Davies, Rose & Co., Ltd., Boston, Mass. (Booth 20), hope that you will visit their headquarters. The preparations that this firm is exhibiting have a world-wide reputation. Physiological or chemical tests are made to assure their standardization. Clinical experience vouches for their dependability. Messrs. R. J. Mansfield and H. V. Orne, who are well known to many of the medical practitioners of New York, will be at the booth to welcome you.

R. B. Davis Co., Hoboken, N. J. (Booth 1). New Food Value Charts (calcium, phosphorus, vitamin D and caloric value) will be available for those who desire same at the booth of the R. B. Davis Company. Visit Booth No. 1 and be served with Cocomalt. This popular food drink supplies rich calcium, phosphorus, Vitamin D content in a particular delicious form.

DeVilbiss Co., Toledo, Ohio (Booth 21), manufacturers of medicinal atomizers, have reserved Space No. 21 for the 1935 convention of the Medical Society of the State of New York to be held May 13, 14, and 15 at the Hotel Ten Eyck, Albany. A complete line of atomizers and vaporizers for both home and professional use will be on display. A prominent feature of the DeVilbiss Exhibit will be the recently developed DeVilbiss Nasal Guard, which prevents any excess pressure in the nasal passages during prescribed self-treatment. E. Manning will be in charge. All delegates to the convention are cordially invited to visit the DeVilbiss display.

Foregger Co., Inc., New York City (Booth 27). Those not already familiar with the carbon dioxid, or filter method of anesthesia may obtain first-hand in-

formation from the pioneer manufacturer of this type of apparatus by visiting the display of the Foregger Company. Oxygen and oxygen-carbon dioxid outfits for therapy and resuscitation are also on display.

E. Fougera & Co., New York (Booth 28). This firm was established in the year 1849. Since then they have devoted their efforts to supplying the medical profession with Swiss, and They invite you Booth 28, Technical Exhibits, and afford their representative an opportunity to explain the merits of the products displayed.

John B. Garrett, Troy (Booth 5). This exhibit will be fitted with the display of the latest Westinghouse achievement, their Shock-Proof X-Ray Equipment, which, incidentally, is priced within the reach of every physician; a complete display showing the entire Bard-Parker line of instruments as well as a full line of pharmaceuticals, suture materials, and surgical dressings.

Gerber Products, Fremont, Mich. (Booth 7). Gerber's new method of Shaker-Cooking will be explained to you at Gerber Products Booth. There are illustrations and charts of this new process and samples open for inspection. Booklets and leaflets are available. Some of these are suitable for distribution by physicians while some are for professional use only.

Harold Surgical Corp., New York City (Booth 22), whose policy it has always been to cater to the complete needs of the physician, will have a very comprehensive exhibit. They will display a complete line of physiotherapy apparatus including diathermy machines, short-wave machines, hot and cold mercury quartz lamps, galvanic and sinusoidal machines. Also a complete line of surgical instruments and diagnostic instruments. They will also have a complete display of Hamilton furniture and other equipment.

H. J. Heinz Co., Pittsburgh, Pa. (Booth 10), creators of the Famous 57 Varieties of Pure Foods, are displaying Strained Foods, Tomato Juice, and Breakfast Cereals especially suited to

Infant Feeding and diet therapy. Do not fail to register for the Heinz Nutritional Charts, a set of reference charts invaluable to the doctor in diet planning.

Intourist, Inc., New York (Booth 25), the Soviet State Travel Company, has prepared an exhibit on Soviet Travel. Information on any aspect of travel in the Soviet Union, as well as free literature, will be offered to physicians in attendance. For the medical profession, travel in the Soviet Union offers more than merely interesting possibilities: There are the famous health resorts of the Crimean Coast and the Caucasus; the organization of public health facilities, the hospitals and clinics, and the various institutions for experimental medicine invite the inspection of American physicians.

Mead Johnson & Co., Evansville, Ind. (Booth 13), will have on exhibit its complete line of infant diet materials including Dextri-Maltose, Mead's Standardized Cod Liver Oil, Mead's Viosterol in Oil, Mead's Cod Liver Oil with Viosterol, Mead's Viosterol in Halibut Liver Oil (liquid and capsules), Mead's Halibut Liver Oil, Mead's Brewers Yeast (powder and tablets), Pabulum, Mead's Cereal, Sobee, Mead's Powdered Protein Milk, Mead's Powdered Lactic Acid Milk, Mead's Powdered Whole Milk, Alacta, Recolac and Casec. There will also be for the examination of physicians a complete line of Mead's services such as "Diets for Children from Four Months to Four Years," height and weight charts, etc., all of which are free to members of the medical profession in any quantity desired. Representatives will be on hand to meet their friends and to discuss the application of any of the Mead products to infant feeding problems.

Kalak Water Co. of New York, Inc. (Booth 24) invites physicians to visit the booth and learn how delicious and refreshing Kalak is when properly served. Obviously, the greatest use for Kalak Water is for routine use in the home when an alkaline water is indicated. It is generally recognized by physicians that the majority of people, and particularly those of sedentary habits, do not drink sufficient water, both for its value as a

food and as an eliminant. Kalak solves this problem, for it combines purity and palatability.

Lederle Laboratories, Inc., New York City (Booth 2). The Lederle exhibit will feature the rapid diagnosis of pneumonia, using Antipneumococcus Typing Serum (Rabbit). They will also show Solution Liver Extract Parenteral for the treatment of pernicious anemia, Gas Gangrene Antitoxin, Erysipelas Antitoxin, Pollen Antigens for Hay Fever, and many other products of interest to the practicing physician.

Mennen Co., Newark, N. J. (Booth 26). This exhibit will again show their two baby preparations—Mennen Antiseptic Oil and Mennen Antiseptic Borated Powder. Last year the Mennen booth was one of the most popular at the Convention; great interest in these two Mennen preparations was shown by those attending. The Mennen Company tell us that they not only will distribute trial sizes of their Antiseptic Oil and Antiseptic Borated Powder, but their very popular line of shaving and after-shave preparations.

Merck & Co., Rahway, N. J. (Booths 8-11). Tryparsamide Merck is the chemotherapeutic agent of choice for the treatment of neurosyphilis. Its use is an office procedure. It is administered intravenously, does not disrupt the patient's daily routine of life, and is inexpensive. Full information can be obtained at the Merck Booth.

Philip Morris & Co., Ltd., Inc., New York (Booth 14). The manufacturers of Philip Morris cigarettes have been studying the effects of smoking on irritation of the mucous membrane of the upper respiratory tract. In the booth, one of its research staff will be available to explain the work and the results obtained. Samples of Philip Morris cigarettes will be distributed.

Mutual Pharmacal Co., Syracuse, N. Y. (Booth 4), will exhibit products of their laboratory. An interesting line of Eye Ointments and new products will be sampled. Physicians are cordially invited to visit the booth.

Radium Emanation Corp., New York City (Booth 8). Our exhibit consists of

applicators used in modern radium therapy, including removable and permanent radon seeds of the composite type with radon under leakproof glass seal. Patented loading slot instruments for implanting seeds. Uterine tubes, cervical applicators, surface plaques, etc., showing methods of filtering radiation.

Sanborn Co., Cambridge, Mass. (Booth 12), announces a new and improved model E-1 METABOLISM TESTER, featuring easy breathing, simplicity of operation and design, and accuracy. Supplied in attractive colors with tables to match. Sanborn Company also announces a redesigned ELECTRIC-PORTO-CARDIOGRAPH, featuring portability and simplicity but still maintaining all essential working parts which contribute to the success of accurate heart testing. See these two up-to-the-minute apparatus at our booth.

Sandoz Chemical Works, Inc., New York City (Booth 3). Our exhibit will feature Council Accepted products: CALGLUCON, in stable, 10 per cent and 20 per cent ampule solution and in palatable oral forms for effective calcium therapy; GYNERGEN, the only product of Ergotamine for uterine hemostasis and the relief of migraine headache; SCILLAREN and SCILLAREN-B, cardiuretic principles of squill; SANDOPTAL, a safe, mild hypnotic for general use.

Saratoga Springs Authority, Saratoga Springs (Booth 29), this year, as for the past three years, will serve Geyser water to the delegates and visitors to the meeting. Geyser is one of the three naturally carbonated mineral waters from the springs at Saratoga Spa which are bottled by the State of New York.

Sorensen Co., Long Island City (Booth 15), will have on display the DeLuxe complete with Coagulator and

Desiccator for all office treatment work. No. 405 Heavy Duty Office Treatment Outfit. Portable Bedside Treatment Outfit No. 65. No. 54 Office Treatment Unit complete with sinus cleanser and tonsil irrigator. Iodine Vaporizer will also be on display for your inspection and comments.

E. R. Squibb & Sons, New York City (Booth 23). Our exhibit will feature several new products recently made available, including physiologically standardized Anterior Pituitary Extract and a new and economical Vitamin A and D preparation. Other Squibb vitamin, endocrine, biological, and arsenical preparations will be on display and competent attendants will be present to discuss these and other Squibb products.

Vegex, Inc., New York City (Booth 16). (Marmite) Exhibit will show from best authenticated data, Vitamin A and the Vitamin B complex needs of man, including nursing, bottle-fed and pre-school children; current feeding tests, showing some factors which increase red blood cell counts; the use of Vegex (Marmite) to determine the intrinsic factor, with authenticated data; and Vegex in alcoholic disorders. Clinical samples with "Vitamins" and literature will be sent to physicians registering.

Winthrop Chemical Co., Inc., New York (also successors to H. A. Metz Laboratories), New York City (Booth 17), in addition to presenting their motion picture, "Modern Methods of Anesthesia," will feature recently introduced preparations, such as EVIPAL, hypnotic, NOVALDIN, analgesic, DIODRAST, urographic medium, MEBARAL, antiepileptic and sedative, DEVEGAN, for leukorrhea, etc. Complete details will also be available on well-established preparations such as Salyrgan, Theominal, the Salvarsans, Novocain, Omnadin, and so on.

HOTEL ACCOMMODATIONS IN ALBANY

For your information, the following page lists hotels in Albany most conveniently located to places of meetings. Rates and maximum accommodations are given, along with facilities for the storage

of automobiles. Make your hotel reservations as early as possible, verify your room, and plan to stay in Albany for the entire session. An unusually interesting meeting is anticipated.

HOTEL DE WITT CLINTON, State and Eagle Sts. Total number rooms 400, rate single from \$3.25, double from \$6.00, European plan, all outside rooms, number available, single 60, double 180, garage not included, 75 cents a day. *Manager, Mr. John J. Hyland.*

HOTEL HAMPTON, 38 State St. Total number rooms 240, rate single, \$2.50 and \$3.00, double \$4.00 and \$5.00, European plan, all outside rooms, number available about 50%, garage not included, 50 cents. *Manager, Mr. Lehman J. Winters.* Suite for two \$7.00 and \$8.00.

CAPITOL HOTEL, 11 Green St. Total number rooms 184, rate single \$1.50 running water, \$2.00 shower, double \$2.50 running water, \$3.00 bath, European plan, outside rooms, number available 75 to 100, garage not included, 50 cents a day. *Manager, Mr. H. L. Laurie.*

HOTEL TEN EYCK, 87 State St. Total number rooms 400, rate single \$3.00, \$3.50, \$4.00, \$4.50, \$5.00, \$6.00, \$7.00 double \$4.50, \$5.00, \$6.00, \$7.00 double beds, twin beds \$5.00, \$6.00, \$7.00, \$8.00, \$10.00. Suite \$10.00, \$12.00, \$15.00. Number available about $\frac{2}{3}$ each type room, minimum price face court, all others outside rooms, European plan, garage not included, 75 cents a day without service, \$1.00 a day with service. *Manager, Mr. Dewey D. Ellis.*

HOTEL WELLINGTON, 136 State St. Total number rooms 500, rate single \$2.50, \$3.00, \$3.50, double \$3.00, \$4.00, \$5.00, \$6.00, European

plan, all outside rooms, number available 150 to 200, garage not included, \$1.00. *Manager, Miss Joan D. Van Slyk.*

KENMORE HOTEL, 76 N. Pearl St. Total number rooms 300, rate single \$1.50, \$2.00 running water, \$2.50, \$3.00 with bath, double, \$3.00 running water \$4.00, \$5.00 with bath, European plan, outside rooms, garage not included, 50 cents a day. *Manager, Mr. Robert Murphy.*

RALEIGH HOTEL, 134 State St. Total number rooms 50, rate single \$1.75, \$2.50 with shower, double \$4.00, \$3.50, \$4.00 with shower, European plan, outside rooms, number available 20 to 25, garage not included, 75 cents a day. *Manager, Mr. Robert B. Tarsey.*

EDITORIALS

Proven Worth

Physicians who were in practice prior to 1921 need no reminder of the benefits that have accrued to the profession from the State Society's Group Malpractice Insurance Plan. Fourteen years ago most of the companies had withdrawn from the field and the rates of the few remaining carriers that issued this type of insurance were mounting alarmingly. Even at the prevailing high rates the protection rendered was not always satisfactory for the carriers were more interested in effecting a cheap settlement than in safeguarding the reputation of the insured.

The Group Insurance Plan was the State Society's answer to the demand for adequate insurance and expert defense against malpractice claims at a rate that physicians could afford to pay. The Aetna Insurance Company was the only carrier in the State willing to participate in such an experiment. From the point of view of both insured and insurer, the results have fully justified the venture. The Group Plan is operated at an expense ratio of from six to eighteen per cent less than that of other stock insurance companies in the State; and the physician who has carried a minimum policy for the fourteen years of the plan has enjoyed a saving of \$5.33 a year on his premiums.

It is not merely in a financial sense that the profession has benefited. Through

this plan organized medicine has been better able to combat the growing racket of unjustified malpractice claims, beside directing the management of individual cases. The practice of settling for a "nuisance value" has been abandoned and unfounded charges are fought to the last resort.

At the present time over 57 per cent of the members of the Medical Society of the State of New York place their malpractice insurance with the Group Plan. The enrollment of a still larger proportion of the membership would naturally increase the benefits to all concerned. This is the only scheme of malpractice insurance that protects the doctor morally as well as financially and gives him the privilege of defense by the competent and experienced counsel of the State Society. Rates are the minimum required to conform to legal requirements and provide thorough-going protection. After 14 years of successful operation the Group Plan remains, as a past President characterized it, one of the most important services the Society offers its members.

Example and Warning

The disclosures that have been made in the past few weeks concerning the Emergency Relief Bureau in New York City are at once an example and a warning of what to expect if the practice of

medicine is placed under bureaucratic control. While the physicians employed by the Work Relief Bureau receive pitifully low wages, with no prospects of an increase in the near or remote future, the salaries of many executives have been raised as much as a third. A full time doctor is lucky to receive \$40 for a long, hard week. The director of the recreational division went from \$5,000 to \$6,800 a year in one jump.

This sort of thing is what the profession would have to look forward to under compulsory health insurance. A few lucky executives, principally lay, would receive substantial salaries for comfortable sinecures, while the mass of physicians would have to struggle 10, 12, and 14 hours a day to gross \$40 or \$50 a week.

In *The Forty Days of Musa Dagh* a minister who has escaped from a deportation train describes the difference between the sympathetic help proffered by individuals and the harsh charity dispensed by bureaucratic organizations. An equally great contrast exists between the individualized service rendered by physicians who are solely and directly responsible for their patients' welfare and the perfunctory routine that passes for medical care when the doctor is a subordinate cog in a complicated bureaucratic machine.

No matter how honest and competent the men at the head of organized relief, the story has been the same all over the country: waste, favoritism and inefficiency. Compulsory health insurance would substitute these inevitable attributes of a political bureaucracy for the high standards and proven responsibility of private medical practice.

Dextrose and the Coronary Circulation

It has been said that when a European loses his money, he commits suicide, but when an American is confronted with financial worries, he develops a coronary thrombosis. The marked increase in the incidence of coronary disease in our country not only affords some substantia-

tion for that statement but has, in addition, presented the medical profession with a scientific problem to solve. Consequently, any contribution which affords a means of preventing or alleviating the dread results of this lesion is indeed welcomed by the physician and layman alike.

It was in 1924 that Edwards and Page called attention to the beneficial effect of the administration of dextrose intravenously upon the hypodynamic hearts of dogs suffering from induced hypoglycemia.¹ Other observers² have since shown the relationship between the sugar content of the blood and appearance of anginal pains. Of particular interest in this connection is that these typical cardiac symptoms appeared in diabetics only at a time when they presented a sugar level below that usual for sufferers from that disease.³ It remained for Gibson and Ross⁴ and Sprague and Camp⁵ to present clinical evidence of the efficacy of intravenous injections of dextrose in the treatment of cardiac disease.

Since pharmacological proof is, in the last analysis, the *sine qua non* of a therapeutic remedy, Ginsberg, Stoland, and Loy⁶ have scientifically investigated the effect of dextrose upon the coronary circulation. Their studies were fourfold in nature; the action on the coronary cir-

⁶ Ginsberg, A. M., M.D., Kansas City, Mo., and Stoland, O. O., Ph.D., and Loy, David T., M.S., Lawrence, Kan.: Studies on The Coronary Circulation. III. Effect of Intravenous Injections of Dextrose on The Coronary Circulation. *Arch. Int. Med.* 55: 42, 1935.

culation in the whole animal, on the denervated heart-lung preparation, on the innervated heart-lung preparation and the practical application of their findings.

Their work is a distinct contribution to medicine. Their most important findings are that continuous or repeated intravenously administrations of dextrose maintain an increased flow of blood through the coronary circulation; that repeated injections are as efficacious as the first administration of the drug; and finally that there are no noticeable changes in either the heart rate or the blood pressure. They find that the intravenous administration of glucose causes a marked increase in the coronary circulation which is evident over a protracted period without any evidence of untoward physiological reaction.

Their experiments further demonstrate that this beneficial influence is not attributable to either a dilator action on the coronary vessels or a decreased viscosity of the blood. Other solutions, such as isotonic sodium chloride, when injected into the blood, resulted in practically no change in the coronary circulation. Even hypertonic solutions of sodium chloride resulted in only a fractional increase in the coronary circulation.

These observers feel that the results of dextrose therapy cannot be accounted for by the simple explanation of hydremia and lowered blood viscosity. While these are factors to be considered, especially since they have shown that dextrose has no effect upon the coronary vessels themselves or upon the nervous centers, other elements must affect the results obtained by animal experimentation; particularly so since other solutions which alter the blood viscosity and water content have not the same effect upon the coronary circulation as the introduction of dextrose intravenously.

The Maternal Instinct

The continuance of species throughout nature seems to be dependent on the mother instinct. Materialistic, mechanis-

tic philosophies, however otherwise logically developed, have been completely demolished by the use of this magic phrase. Poets throughout the ages have become immortal through song dedicated to this supernatural instinct, and theologians have used it as their supreme argument for proving the existence of a "divine power" working in man.

Other aspects of the analysis of this important question are now opening up and are being subjected to a more scientific rationalization. The Freudian school has rendered excellent service in a very necessary "debunking" process, in throwing grave doubts on the utter perfection of the underlying motives of this "instinct." The pioneer experiments of Riddle¹ and his co-workers have shown that mother instinct may be induced artificially by the injection of the appropriate hormone, dosed to obtain maximum reaction.

By the use of prolactin and follicle-stimulating hormone from the anterior pituitary to arouse the ovaries in immature rats to one full cycle of activity (estrin and progesterone production), and the subsequent injection of prolactin, these investigators were able to reproduce most of the poetical phenomena usually observed. Eighteen virgin rats from four litters, aged 67—81 days, isolated from males from their thirtieth day of life, were injected. The fullest expression of maternal behavior obtainable in these virgin rats consisted in retrieving of wandering young, followed by cuddling, covering the young with the older rat's own body. Nest building, when the nesting material was placed directly over the young, seemed definitely to indicate a true but lower level of development of the maternal instinct. There was obtained a development of high degree in five of the ten cases. The fuller expression of the instinct appeared six days after beginning prolactin treatment in one case, at seven days in one case, at eight days in two cases and at eighteen days in another.

¹ Riddle, O., Lahr, E. L., and Bates, R. W.: *Proc. Soc. Exp. Biol. and Med.* 32: 730, 1935.

With the alarmist reports now circulating about the disappearance of the maternal instinct in modern emancipated women, it is a comfort to realize that this deficiency may soon be remedied at any corner drug store—and that the future of the human race is not imperiled.

The Annual Meeting

The physicians of the State should begin looking ahead to May. During the week of May 12, the annual meeting of the Medical Society of the State of New York will convene at Albany. The House of Delegates meets to decide important issues and determine policy. The considered opinions of County societies expressed in resolutions will receive con-

sideration and action. The membership in the House is truly representative of a cross section of the whole profession in the State:

Interested as most physicians are, in these trying times, with the questions which concern him and his economic position, no less important to him will be the scientific sessions, at which fellow members will present their experiences for the benefit of all. Both the technical and the scientific exhibits will be a course in education well worth studying. Last, but not least, the meeting will afford that opportunity for relaxation, social intercourse and reunion which physicians appreciate more than any other group.

Reserve for yourself, the time to meet with the rest of us, in Albany.

Current Comment

A form of medical poverty is developing as the result of too much state and private paternalism, which results in forcing many to abandon private practice and accept merely a living wage from the state. The property of six physicians has been sold for taxes, and five others, poverty stricken, committed suicide, reports the Paris staff correspondent of the *J. A. M. A.*, January 10, 1935.

Caveat Medicus, says the *Catholic Union and Times* of Buffalo, November 29, 1934. "Socialized medicine and dentistry are nothing more than a communistic conception of the services the state should render to its citizens."

H. Lyons Hunt, Director General of the American Medical Editors' and Authors' Association, in a letter says that there are 750,000 pounds of opium imported into the United States annually. Ten thousand pounds are used legitimately—seven hundred and forty thousand pounds are bootlegged at from one to three dollars a grain.

"Labor is now demanding five hours as a day's work, and will get it if it is within the power of the politician to give it. . . . The injustice of the new social structure is quite evident when you stop to think of it. The man who gets paid for twelve hours and works only five is now beginning to cry out

about 'the high cost of sickness, we must socialize medicine.' It will be a sad day for the sick when the doctor becomes a hireling for the Government—progress, ambition, and individual initiative will cease; the public will receive just what it pays for—*mediocrity*." Thus says Dr. John W. Daniel of Savannah, Ga., former President of the Medical Association of Georgia.

Dr. James F. Rooney of Albany, replying to an editorial in the *New York Times* of March 1, 1935, pleading for fairness on the part of public newspapers, said: ". . . you assure your readers that there will be no outburst that police alone will not be able to quell. 'Our real dangers' you say 'are of another sort.' They lie less in violence or the threat of it, than in a deterioration of public morale, a credulous belief in the ability of the government to give everybody a living, a slow undermining of the principles and methods of our institutions as we have long known them. There are 100,000 physicians in the United States who have expressed themselves through the House of Delegates of the American Medical Association at its Chicago meeting a few days ago, as opposed to health insurance. . . . We have tried, and with fair success, to place the interest of the patient above our own. And the almost unanimous expression of the profession's opinion is against health insurance."

The anti-vivisectionists, in spite of their vicious propaganda and unequalled misrepresentation of facts, have rarely been successful in having legislation passed that would abolish all animal experimentation, says Dr. A. C. Ivy of the Department of Physiology of the Northwestern University Medical School (*Medical Economics*, March, 1935). The next step is to introduce a bill to exempt the dog. Dog exemption is simply an opening wedge.

Dr. H. Sheridan Baketel, editor of *Medical Economics*, calls for action: "... Statements of Policy, Resolutions and Recommendations are only initial steps." He asks a formal statement of association policy as to opposition to health insurance.

All who would inform themselves on the "Veterans Racket" should read I. K. Brown's concise account of the Veterans Racket in the March issue of *Medical Economics*. The medical profession is one of the chief sufferers from "the veterans racket" and it should take an active part in attempts to abolish it. "After more than a decade of exploitation, the doctor must awaken to the fact that in politics, at any rate, he does not serve who only stands and waits."

Now that the measure to end medical abuses under the Workmen's Compensation

Law has been passed and signed, it behooves the County societies to start activity, and the establishment of a fair fee schedule is very important. "*All fees and other charges for such treatment and services shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living,*" states the law. The State Industrial Commissioner is empowered to establish a schedule of fees to be charged by physicians. County Society action should soon be taken to have action conform to the requirements of the law by the Industrial Commissioner.

Even the osteopaths, in annual session of their Eastern Osteopathic Association, reported in the *New York Times* of April 1, warn on state medicine. Dr. Russell C. McCaughan of Chicago, executive secretary, said among other things, "that the public had raised the standards of a physician's education to an almost prohibitive cost, but had at the same time reduced the average doctor's remuneration to a deplorably low level. . . ." He warned against the adoption of a "nation-wide experiment" of state medicine, at a time when it is impossible for people "to think calmly." He warned against socializing of the profession through Health Insurance, because it would lower standards. "The public suffers the consequences in substandard treatment."

CATHOLIC DOCTORS ORGANIZING

The Federated Catholic Physicians' Guild has formed or is planning chapters at Little Rock, Arkansas; Belleville, Illinois; Newark, New Jersey; Wichita, Kansas; Scranton, Pennsylvania; Baltimore, Maryland, and Washington, D. C. Its official journal, the *Linacre Quarterly*, sees the time not far distant when the Guild "will stage a na-

tional convention simultaneous with the American Medical Association's Convention and at the same place."

"Then," the publication says, "it will be possible for the Catholic doctor to become articulate in laying down soundly scientific principles with regard to medical and moral problems."

"GOD'S POOR"

In a strong editorial on clinic abuses the *Rhode Island Medical Journal* remarks that "we do not know very much about 'God's poor.' We do not know how many of them are really poor, how many have radios, autos, good clothes, and go to the movies. In the old days poor people were poor people, now the ward cases have boudoir caps and lace nighties. Hot house flowers adorn the sick room which undoubtedly hastens convalescence and saves the hospital expense thereby. When the patient goes home, a follow-up system sees that medical care is continued and a social worker, *e pluribus unum*, sees that medical care is continued and notes the success of

the operation or treatment. This would be a good time to note, in addition to factors of medical interest, the surrounding conditions such as luxuries, radios and other evidences of well being. Now it may be that this system is in force, but we have never seen such a report. There seems at the present time to be a total disappearance of what used to be called self respect. Where are the poor but proud? The present day mind is an unprincipled mind. Why should I pay for a thing which I can get for nothing? Gone is the type of mind which, when overtaken by sickness, *et cetera*, and scrapes in a small way until he has discharged his financial obligation."

Society Activities

Committee on Legislation—March 28, 1935

PROVISIONS OF MEDICAL ABUSES BILL REQUIRING COUNTY SOCIETY CO-OPERATION

The Governor signed the Medical Abuses Bill today in the presence of a large group of its sponsors, among whom was Dr. Arthur J. Bedell, President of the State Medical Society. The bill which now becomes law will depend in a large measure for its success upon the effective co-operation of the State Medical Society and the component County societies.

The features which relate to the County societies are stated below. It is highly important that every County society should immediately take steps toward carrying out the provisions of the law which are its responsibility.

AUTHORIZATION OF PHYSICIANS

Sec. 13-b. Authorization of physicians by commissioner. 1. The commissioner shall upon the recommendation of the medical society of each County or of a board designated by such County society, or by a board representing duly licensed physicians of any other school of medical practice, authorize physicians licensed to practice medicine in the State of New York to render medical care under this chapter. If, within sixty days after the commissioner requests such recommendations, the medical society of any County or board fails to act, or if there is no such society in a County, the commissioner shall designate a board of three qualified physicians, who shall make the requested recommendations. No such authorization shall be made in the absence of recommendation of the appropriate society or board or of review and recommendation of the industrial council.

PERSONS OTHER THAN PHYSICIANS WHO MAY RENDER MEDICAL CARE

No person shall render medical care under this chapter without such authorization of the commissioner, provided, that:

(a) Emergency (first aid) medical care may be rendered under this chapter by any physician licensed to practice medicine in the State of New York without authorization by the commissioner under this section; and

(b) a licensed physician who is a member of a constituted medical staff of any hospital may render medical care under this

chapter while an injured employee remains a patient in such hospital; and

(c) under the active and personal supervision of an authorized physician medical care may be rendered by a registered nurse, physiotherapist or other person trained in laboratory or diagnostic technics within the scope of such persons' specialized training and qualifications. This supervision shall be evidenced by signed records of instructions for treatment and signed records of the patient's condition and progress. Reports of such treatment and supervision shall be made by such physician to the commissioner on such forms and at such times as the commissioner may require.

FACTS TO BE PRESENTED BY PHYSICIANS SEEKING AUTHORIZATION

2. A physician licensed to practice medicine in the State of New York who is desirous of being authorized to render medical care under this chapter, shall file with the medical society in the County in which his office is located, or with a board designated by such society, or by a board designated by the commissioner. In such application he shall state his training and qualifications and shall agree to limit his professional activities under this chapter to such medical care as his experience and training qualify him to render. He shall further agree to refrain from subsequently treating for remuneration, as a private patient, any person seeking medical treatment in connection with, or as a result of, any injury compensable under this chapter, if he has been removed from the list of physicians authorized to render medical care under this chapter, or if the person seeking such treatment has been transferred from his care in accordance with the provisions of this chapter.

RECOMMENDATION BY COUNTY SOCIETY

The medical society or a board designated by it, or by a board as otherwise provided in section thirteen-b, if it deem such licensed physician duly qualified, shall recommend to the commissioner that such physician be authorized to render medical care under this chapter, and such recommendation and authorization shall specify the character of

the medical care which such physician is qualified and authorized to render under this chapter. A licensed physician may present to the medical society or board evidences of additional qualifications at any time subsequent to his original application. If the medical society or board fails to recommend to the commissioner that a physician be authorized to render medical care under this chapter, the physician may appeal to the industrial council.

WITHDRAWAL OF AUTHORIZATION

Sec. 13-d. Removal of physicians from lists of those authorized to render medical care.

1. The medical society or board that has recommended the authorization of physicians to render medical care under this chapter shall investigate, hear and determine all charges of professional or other misconduct by any authorized physician, or by any compensation medical bureau licensed as herein provided, under rules and procedure to be prescribed by the industrial council of the department of labor and shall report evidence of such misconduct, with their determination thereon, to the commissioner. Such investigation, hearing, report and determination may be made by the board of an adjoining County upon the request of the medical society of the County in which the alleged misconduct or infraction of this chapter occurred. The industrial council of the department may review the determination of such medical society or board, and on application of the physician accused must do so, and may reopen the matter and receive further evidence. The decision and recommendation of such industrial council shall be final, binding, and conclusive upon the industrial commissioner.

CAUSES FOR WITHDRAWAL OF AUTHORIZATION

2. The commissioner shall remove from the list of physicians authorized to render medical care under this chapter the name of any physician who he shall find after reasonable investigation is disqualified because such physician:

(a) Has been guilty of professional or other misconduct or incompetency in connection with medical services rendered under this chapter; or

(b) has exceeded the limits of his professional competence in rendering medical care under this chapter or has made materially false statements concerning his qualifications in his application for the recommendation of the medical society in the County in which his office is located, or of the board designated by it, or of a board as provided in section thirteen-b; or

(c) has failed to submit full and truthful medical reports required to be made by him to the commissioner, or the industrial board; or

(d) has rendered medical service under this chapter for a fee less than fixed by the commissioner as the minimum rate in his locality; or

(e) has participated in the division, transference, assignment, rebating, splitting, or refunding of a fee for medical care under this chapter; or

(f) has solicited, or has employed another to solicit for himself or for another the professional treatment, examination or care of an injured employee in connection with any claim under this chapter.

MEDICAL SOCIETY MAY INVESTIGATE CHARGES

A medical society or board may upon direction of the commissioner or upon its own motion investigate the alleged disqualification, as defined in this section, of any physician whose authorization to render medical care under this chapter it had previously recommended, or the alleged grounds for revocation of the license of any compensation medical bureau whose licensing it had previously recommended. Such physician or bureau shall be notified of the charges against him or it and shall be given reasonable opportunity to be heard and to present evidence in his or its behalf. Upon the completion of its investigation such society or board shall communicate its findings to the commissioner and to the physician or bureau whose conduct was investigated, and shall file with the commissioner a record of the evidence upon which such findings were based.

PAYMENT OF MEDICAL FEES

Sec. 13-f. Payment of medical fees.

(1) Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by section thirteen-b of this chapter to render medical care under this chapter, or to the agent or to the executor or administrator of the estate of such physician. No physician rendering treatment to a compensation claimant, shall collect or receive a fee from such claimant within this State, but shall have recourse for payment for services rendered only to the employer under the provisions of this chapter. Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services.

(2) Whenever his attendance at a hearing is required, the physician of the injured employee shall be entitled to receive a fee from the employer, or carrier, in an amount

to be fixed by the commissioner in addition to any fee payable as a witness in a civil action.

PAYMENT OF BILLS FOR MEDICAL CARE

Sec. 13-g. Payment of bills for medical care.

(1) Unless within thirty days after a bill has been rendered to the employer by the physician or hospital which has treated an injured employee, such employer shall have notified the commissioner and such physician or hospital in writing that such employer demands an impartial examination of the fairness of the amount claimed by such physician or hospital for his or its services, the right to such an impartial examination shall be deemed to be waived and the amount claimed by such physician or hospital shall be deemed to be the fair value of the services rendered by him or it.

(2) If the parties fail to agree as to the value of medical aid rendered under this chapter such value shall be decided by an arbitration committee consisting of two physicians designated by the president of the medical society of the County in which the claimant resides, and two physicians, also members of the medical society of the State of New York, appointed by the employer or carrier. The majority decision of the arbitration committee shall be conclusive upon the parties as to the value of the services rendered. In the event of equal division, the committee shall select a fifth physician, also a member of the medical society of the State of New York, whose decision shall be conclusive.

(3) The parties to arbitration proceedings under this section shall each pay to the industrial commissioner a sum equal to five per centum of the amount payable under such decision, or a minimum of two dollars, whichever is greater. From sums so collected the commissioner shall pay to each member of the arbitration committee, a per diem fee of ten dollars for each arbitration session attended.

LICENSING COMPENSATION MEDICAL BUREAUS

Sec. 13-c. Licensing of compensation medical bureaus. (1) The commissioner may, upon the recommendation of the medical society of each County or of a board designated by such county society, or of a board as provided in section thirteen-b, authorize and license compensation medical bureaus, maintained by qualified physicians wholly or principally for the diagnosis and treatment of industrial injuries or illnesses in respect of which they are authorized to render medical care under this chapter. Application for such authorization shall be

made on forms to be furnished by the commissioner and shall disclose in full the nature of the personnel and equipment of such bureaus. No such authorization shall be made in the absence of recommendation from the appropriate society or board. Each such bureau which received such authorization shall:

(a) Make reports on its personnel and equipment in such form and at such times as may be required by the commissioner; and

(b) be subject to inspection by the commissioner or the medical society of the County in which such bureau is located; and

(c) pay to the commissioner a license fee of fifty dollars per annum for each office of such bureau.

EMPLOYMENT OF SPECIALISTS

(d) The industrial board, on its own motion, or a referee, upon the recommendation of the chief medical examiner for the workmen's compensation division, hearing a claim for compensation may require examination of any claimant by a physician especially qualified with respect to the diagnosis or treatment of the disability for which compensation is claimed; and may require a report from such physician on the diagnosis, the causal relationship between the alleged injury and subsequent disability, proper treatment, and the extent of the disability of such claimant. The physician to conduct such examination shall be designated by the commissioner from a panel of especially qualified physicians submitted to him by the medical society of the County, or any other board acting for any school of medical practice. Additional names for such panel shall be furnished by the society whenever requested by the commissioner and if such request is not complied with in thirty days the industrial commissioner may add thereto names of his own selection. The employer or his insurance carrier shall pay for such examination in an amount to be directed by the industrial commissioner.

From the above excerpts it is obvious that County societies must either as a body or through a properly created committee be prepared to do the following, and the first must be completed within 60 days after July 1:

1. Prepare list for Commissioner of Labor.
2. Investigate charges: (a) at direction of Commissioner; (b) on its own initiative.
3. Arbitrate differences in fees.
4. Pass upon request for licenses by compensation bureaus.
5. Prepare list of specialists.

There are other important features in the bill in which the County society does not have a responsibility, as, for instance the conduct of laboratories, provisions for hospital treatment, addition of physicians to the Industrial Council, provision for minimum fee schedule, and so on.

Copies of the complete law will be sent out as soon as it is printed.

Committee on Legislation

Sub-Committee on the Deaf and Hard of Hearing

This sub-committee, acting under the authority of both the Committee on Public Relations and the Committee on Public Health, and with the approval of both these standing committees, desires to make an informative announcement to the members of the Medical Society of the State of New York.

Co-operation of the medical profession is earnestly sought by the sub-committee for two objectives: (1) Raising the standard of otological care of children in schools for the deaf; and (2) working for conservation of hearing of all school children.

All physicians are urged to report to the State Department of Education children discovered to be deaf and in need of special care. These children include the congenital or hereditary types as well as those who

lost usable hearing before speech was established. These cases should be reported to the Bureau of Special Schools.

Children whose hearing is impaired present a different problem. This committee advocates an annual school hearing program for all children for the purpose of early discovery of potential as well as permanently impaired hearing. It is well known that many cases can be cleared up by medical care promptly given and that many others may be arrested or even improved by means of treatment. When neglected these cases suffer a heavy life handicap which limits earning power and induces numerous personality problems. This is not necessary if early discovery be made the rule and if parents are encouraged to refrain from concealing a condition which they feel to be disgraceful.

Pending the extension of the State school hearing program, which is gradually coming into operation, all cases of impaired hearing in children should be reported to the Bureau for Handicapped Children.

The preschool child should not be overlooked. Early education of young deaf children is important. The committee urges that young deaf children be reported and also preschool hard of hearing children whenever discovered.

Medical Broadcasts

Under the auspices of the Medical Information Bureau of the New York Academy of Medicine, the following radio broadcasts are scheduled from WABC:

Thursday, April 18, 1935, 1:15 P.M., 15 minutes.
Speaker: Dr. Walter C. Klotz, Assistant Professor, Department of Public Health,

Cornell Medical College. Subject: "Modern Methods in Treating Tuberculosis."

Thursday, April 25, 1935, 1:15 P.M., 15 minutes.
Speaker: Dr. Alfred E. Shipley, Deputy Commissioner, Department of Hospitals, New York City. Subject: "Hospitalization of the Tuberculous."

The public mind seems so confused by the medical claims of all sorts of unqualified healers that a western medical journal suggests that the orthodox physician help educate the public by decorating his reception room with portraits of the leaders of medicine like Pasteur, Lister, Osler, and Banting, with brief inscriptions relating their achievements. The magazines on the reading table, too, can be of a kind to impart correct health information, such as *Hygeia*,

and, to bring the moral home, the doctor's framed certificate of affiliation with his State and County medical societies will complete the evidence.

A modern small boy with great attention watching the stethoscope being used on a member of his family: "What station did you get, Doctor?"—*School Physicians' Bulletin*.

CONTEMPORARY VIEWS OF ANGINA PECTORIS AND OF CORONARY THROMBOSIS

LEWELLYS F. BARKER, M.D.

BALTIMORE, MARYLAND

Introduction

In a discussion of angina pectoris and of coronary artery thrombosis for the general practitioner it is of note that important advances in the existing knowledge of the coronary circulation and the disorders to which it is liable have been made during the past few years. With the prolongation of the average duration of life that has resulted during the past few decades from the better prevention and control of the maladies of youth, the diseases of the heart that develop in middle and later life now stand perhaps foremost in interest for the general practitioner. And, aside from the valvular diseases of the heart, it is the disturbances of nutrition of the heart that are due to alterations in the flow of blood through that organ that especially challenge medical attention. It is but little wonder then that medical investigators have devoted much time and work to the study of the anatomy, physiology, and pathology of the heart muscle and of the clinical pictures that arise from the nutritional disturbances of the muscle fibers that owe their origin to altered structure and function of the blood vessels and nerves of the heart or to changes in the general circulation and in the body metabolism. Of these clinical pictures, those of arteriosclerosis, of arterial hypertension, of angina pectoris, and of thrombosis of the coronary arteries have been studied so heart are the most important.

Blood-Supply and the Innervation of the Heart Muscle

Important advances have been made in the existing knowledge of the blood-supply of the heart and of the distribution and function of the nerves that go to and

from the heart. The right and left coronary arteries have been studied so intensively that there has been attained a familiarity with all their sub-divisions from their origin at the root of the aorta to their terminations in precapillary and capillary domains. Improvements in the anatomical technic of injection, and especially the introduction of the method of injection with contrast substances like iodipin followed by stereoscopic x-ray examinations, have made it possible for anatomists to visualize the coronary blood-supply throughout its whole extent both in normal and in diseased hearts.

The findings on use of these methods and the observations after experimental ligation of branches of the coronary arteries in animals have given entirely new conceptions of the blood supply of different parts of the heart muscle and of the relations of the ultimate sub-divisions of the right and left coronary arteries to one another. Results of studies in this connection are of greatest clinical interest and will be referred to briefly.

Though, in general, the right coronary artery supplies the right side and the left coronary artery the left side of the heart, that is not an invariable rule. The *right coronary artery* runs to the right and backward in the coronary sulcus and then sends its posterior descending ramus downward in the posterior longitudinal sulcus so as to arrive close to the apex of the heart; through its branches it supplies the right auricle, most of the right ventricle (not all of it), the posterior third of the interventricular septum, and sometimes a large part of the posterior surface of the left ventricle as well as contributing to the supply of the medial (posterior) papillary muscle of the left ventricle.

Read at the meeting of the Academy of Medicine, Rochester, New York, October 4, 1934

The *left coronary artery*, larger than the right, divides almost immediately into two branches: (1) the *anterior descending ramus* that runs downward in the anterior longitudinal sulcus as far as the incisure of the apex and goes over upon the diaphragmatic surface of the heart, and (2) the *circumflex ramus* that runs in the coronary sulcus to the left and then upon the diaphragmatic surface of the heart to the right (though it does not extend as far as the posterior longitudinal sulcus); these rami of the left coronary artery supply blood to most of the left auricle and ventricle, to the anterior two-thirds of the interventricular septum, and to a narrow strip of the anterior surface of the right ventricle along the ventricular septum, as well as participating in the blood supply of the large right papillary muscle in the right ventricle.

With regard to the blood supply of the papillary muscles, it should be kept in mind that in the right ventricle the two medial papillary muscles are supplied by the right coronary artery only, whereas the large lateral (anterior) papillary muscle receives blood from both coronary arteries; in the left ventricle the large anterior (lateral) papillary muscle is supplied by the left coronary artery only, whereas the smaller posterior (medial) papillary muscle receives blood from both coronary arteries.

The blood supply of the important *atrioventricular conduction system* has also been carefully worked out. Here the right coronary artery supplies the Aschoff-Tawara node, and usually also the His bundle as well as the posterior part of the left branch of the bundle, whereas the left coronary artery supplies the right branch of the bundle and the anterior part of the left branch of the bundle. A knowledge of this distribution should in the future be helpful in interpreting the conduction-disturbances that are due to interference with blood supply.

Formerly, it was believed that the branches of the coronary arteries are all so-called "end-arteries" which do not undergo anastomosis in their peripheral distribution, a belief that was at the basis of Cohnheim's interpretations of the origin of infarctions of the heart. But more exact studies during the present century have proven that the coronary

arteries undergo innumerable anastomoses through minute branches within the heart muscle and to a lesser extent through anastomoses on the outer surface of the heart just under the epicardium. There appear to be, however, some differences in the anastomoses in different hearts, a fact that may account for certain variations in behavior of the heart muscle of different persons in coronary occlusion. Despite these proven anastomoses, coronary occlusion (by thrombosis in man or by ligature in experimental animals) causes infarction of the heart since the anastomoses are insufficient to maintain normal nutrition in the domain of distribution of the occluded artery. When parts of the heart muscle have a restricted coronary blood supply some blood may still reach these parts by way of the Thebesian system (Wearn; Grant and Viko).

An interesting anatomical difference between the branches of the left coronary artery and those of the right lies in the fact that the former go off from the main branches almost at a right angle into the wall of the left ventricle, whereas the latter go off obliquely into the wall of the right ventricle. Every single heart muscle cell, as Wearn has shown, has its own capillary blood supply.

As to the relation of blood flow through the coronary circulation to the systoles and diastoles of the heart, there have been two sharply opposed views. One group of investigators assumes that the main flow occurs during systoles and is dependent upon systolic blood pressure; whereas a second group maintains that systoles offer strong resistance to flow within the coronaries and that blood enters them chiefly during diastoles and the flow is accordingly largely dependent upon the diastolic blood pressure in the aorta. Though the matter is still under dispute it would seem to be less important than the determination of the amount of blood that passes through the coronary circulation each minute, and many calculations of this for man (at rest and on exertion) have been made by cardiologists. Newer studies have shown that the blood supply to the heart is regulated according to alterations in various circulatory factors (especially blood pressure and heart rate). In this regulation, the vagus and the sympathetic nerves play an important rôle,

for on vagal stimulation the coronary arteries undergo constriction, whereas on sympathetic stimulation they become widened. Just what part is taken by the intrinsic nerve fibers and ganglion cells of the heart walls in cardiosensory, cardiomotor and vasomotor functions is still rather obscure.

Clinical Picture of Angina Pectoris

Every physician in general practice must frequently see patients who suffer from angina pectoris. The symptoms in a typical severe attack are so characteristic that the condition can usually be recognized immediately. The patient, usually in middle or later life, is suddenly attacked (during exertion or exposure to cold, or during some emotional excitement) by severe pain in the region of the heart or behind the upper or middle part of the sternum. The pain is afterwards described as having been "agonizing," "frightful," or "unbearable," is accompanied by a feeling of intense anxiety and often also by a vise-like sense of constriction in the chest; it often radiates into the left arm and hand, sometimes into other parts of the chest, the neck or the back, or, occasionally, into the right arm. Usually the patient remains almost immobile while the severe pain lasts; he may groan but usually does not talk. The expression of the pale face reveals his anxiety and suffering. His hands may be cold and clammy. There is, as a rule, no shortness of breath, nor does he vomit or show signs of collapse. The pulse rate is, as a rule, not accelerated, though the blood pressure may rise slightly in the attack. After a few minutes, especially if a nitroglycerine tablet be placed under the tongue, or amyl nitrite from a crushed pearl be inhaled so that the face becomes flushed, the pain may cease with experience of a sense of great relief. Often, however, after the administration of the nitrites, some pain in the chest may still continue for a half hour or longer, even if heat be applied to the hands or over the heart.

The practitioner of large experience sees every degree of severity of attacks of angina pectoris from those accompanied by extreme pain and sense of impending death to those that are so mild that their nature may scarcely be suspected.

Statistics recently collected by Eppinger and Levine indicate that angina pectoris affects four times as many men as women, that the average age of onset is in the fifties, that patients often have arterial hypertension, that heredity is important as an etiological factor, and that the average duration of life after the first attack is about four and a half years. Many of course die sooner, but many live very much longer. About half of the patients die suddenly, though not always of coronary thrombosis. In the slower deaths, coronary thrombosis was the cause of death in 30 per cent, whereas less than 10 per cent died of congestive heart failure.

Theories as to the origin of attacks of angina pectoris have been much discussed. That of widest acceptance is the "coronary theory" that assumes sclerosis of the coronary arteries leading to narrowing of their lumina or spasm of the coronary arteries, or a combination of the two, the pain arising directly in the spastic diseased artery or indirectly in the ischemic heart muscle. Opposed to this "coronary theory" is the "aortic theory" that assumes either that the pain is due to distention of a diseased aorta (Allbutt), or to sudden stasis of blood in the root of the aorta and the proximal portions of the main trunks of the coronary arteries (Wenckebach).

Much can be said in favor of each of these theories, though strong objections can also be raised against each of the two views. In 1933 Parade of Stepp's clinic in Breslau in an exhaustive review of the whole subject arrived at the conclusion that in an attack of angina pectoris the condition of the blood supply of the heart is such that any increased demand made upon the heart leads to temporary insufficient nourishment of one or several local areas of the heart muscle. In other words there is a disturbance of the capacity to adapt the local blood flow to the work called for from the heart, and when local areas are insufficiently supplied with blood, the pain of angina pectoris arises—a warning, as it were, to the patient that the demands upon the heart muscle must be lessened! He seems to think that the actual pain arises in the walls of the heart in the small local areas that are not receiving enough blood to meet the local

demands for blood. American clinicians also tend to believe that the origin of the pain in angina pectoris must be attributed to temporary anoxemia of areas of the heart's wall.

Clinical Picture of Coronary Artery Thrombosis

To consider next the sudden occlusion of a branch of a coronary artery by a thrombus (coronary thrombosis with infarction of the heart), there is approached a clinical syndrome that has only relatively recently become easy of recognition even in typical cases. In the ten years preceding 1931, coronary thrombosis was correctly diagnosed in only 43 per cent of the cases that came to autopsy at the Presbyterian Hospital in New York (Levy; Bruenn and Kurtz).

Cary Eggleston reported on coronary thrombosis in the last edition of Cecil's *Textbook of Medicine*, though Dock had recognized the condition during life in one patient and confirmed it at autopsy as early as 1896. A few cases had been reported by Russian and Germany physicians in 1910 and 1911, and J. B. Herrick of Chicago in 1912 had emphasized the fact that coronary thrombosis is a clinical entity that is quite clearly recognizable during life. It was not until about 1918 that general medical interest in the condition became extensively aroused. Since then many important papers have been published and physicians in hospitals and private practice make the diagnosis easily in the typical cases.

European observers (J. Hay, 1933; G. W. Parade, 1933) pay respect to American investigators (J. B. Herrick, F. M. Smith, Libman, Levine, Pardee, Longcope, Wearn, Christian, Oppenheimer and Rothschild, and others) for focussing attention upon coronary thrombosis and for establishing the main clinical and electrocardiographic features. Since their fundamental work many further contributions have been made by Americans and by Europeans. Commendable reports of Americans include Barnes and Whitten, S. A. Levine, M. H. Kahn, W. J. Kerr, E. B. Krumblhaar, Pardee and Master, W. J. Wilson, and Wolferth and Wood. The European papers of A. G. Gibson (1925), J. W. McNee (1925), Parkinson and Bedford

(1928), J. Hay (1933) and G. W. Parade (1933) deserve especial mention.

Clinically, in typical cases, the most characteristic feature is the long-continued severe pain that as a rule appears independent of exertion or emotion (sometimes awaking a patient who is asleep) and is referred to a lower area in the chest than the site of the pain of ordinary angina pectoris, being maximal behind the lower third of the sternum or in the upper abdomen. This pain is usually accompanied by extreme anxiety and a sense of impending death. Instead of remaining immobile as in angina pectoris, the patient is often restless, changing his position frequently or even attempting to walk about. The pain may continue for hours or days despite rest and medication; it is not relieved by nitrites and can only be somewhat assuaged by large doses of morphine.

This persistent severe pain corresponds to the "status anginosus" of the older literature. Nausea, vomiting, and dyspnea are common. The pulse rate is accelerated, the heart sounds are feeble, the blood pressure (owing to the rapid weakening of the left ventricle) usually falls considerably within a few hours (though a brief initial rise may be observed), and the pulse becomes feeble, often scarcely perceptible. Collapse symptoms are present from the start (cold-sweat, ashy-gray color and cyanotic lips, and later profound weakness). Slight fever develops, as a rule, accompanied by a polymorphonuclear leukocytosis (sometimes 15,000 W.B.C. or more). Occasionally, a pericardial friction rub develops; signs of pulmonary edema are often discernible. When such a syndrome has appeared, one can be practically certain that coronary occlusion (thrombosis) has occurred, even without aid of a corroborative electrocardiogram.

The severity of the symptoms varies with the site and extent of the area of heart muscle that is deprived of its blood supply. When the area is relatively small, the symptoms may be so mild as to make impossible a positive diagnosis without the aid of an electrocardiogram, but it should be emphasized that clinicians feel that by far the majority of cases, mild and severe, can be diagnosed with practical certainty in the absence of an electrocardiographic tracing.

Even in the milder cases, the site and distribution of ache or pain that arises spontaneously (without relation to effort or emotion) and persists for a longer time despite repose, mental calm and the administration of nitrites or morphine, permit the making of the diagnosis of coronary thrombosis. If not certain, but suspicious, of thrombosis, the physician, keeping the patient at absolute rest in bed, will watch for the development of slight fever with leukocytosis or for the appearance of a transient friction rub. If the diagnosis continues to be in doubt, an electrocardiogram will usually be decisive; this can easily be made in hospitals, or a portable machine may be taken to the patient's home to make a tracing.

The cases of coronary thrombosis most likely to lead to an erroneous diagnosis are: (1) Those in which the pain is abdominal (simulating an acute surgical condition in stomach, intestine, gall-bladder, appendix, or urinary tract, which may be accompanied by fever and leukocytosis); or (2) those in which the dominant symptoms are dyspneic or syncopal and are not accompanied by pain. In such cases, a sudden and unexplained fall in blood pressure, or a history of earlier mild anginal pains may arouse suspicion, especially if the patient be of middle age or older, and any signs of arteriosclerosis can be made out. In such bizarre syndromes, a positive diagnosis may not be possible without the aid of an electrocardiogram. More than once, in the absence of adequate study, surgical exploration of the abdomen has been resorted to with the mortification of negative findings!

In about 85 per cent of the cases (according to Parade), it is the anterior descending ramus of the left coronary artery that is thrombosed so that it is the syndrome due to this lesion that the general practitioner is very likely to encounter. (Barnes and Ball [1932] in their series of 1,000 cases found a lesser incidence for infarction of the anterior descending ramus of the left coronary artery.)

When the lesion is in the right coronary artery, it is usually situated in the horizontal branch that supplies a large part of the posterior wall of the left ventricle so that the infarction is located

there (Whitten). In the rare instances in which the whole of the right coronary artery is thrombosed, acute insufficiency of the right side of the heart develops with stasis phenomena (pulmonary edema, enlargement and tenderness of the liver, and engorgement of the peripheral veins). Moreover, since the atrioventricular conduction system receives its blood supply from the right coronary artery chiefly, marked disturbances of stimulus formation or of stimulus conduction (other than bundle branch block) developing after an attack points to involvement of the coronary artery of the right side rather than to that of the left.

Ordinarily infarction of the anterior wall of the left ventricle with involvement of the apex and the anterior part of the interventricular septum is of graver prognosis than infarction of the posterior wall of the left ventricle (F. C. Wood).

Electrocardiograms in Angina Pectoris and in Coronary Thrombosis

Since electrocardiography has been applied, especially here in America, to the study of patients suffering from angina pectoris or from coronary thrombosis, acquaintance with the different E K findings in the two syndromes has been gained. Whereas in ordinary uncomplicated angina pectoris there may be slight alterations of the curve (most often a lowering of the level of the tracing of the R-T interval in leads I and II), in the infarction of the myocardium that follows coronary thrombosis in human beings (or ligation of the coronary artery in experimental animals), there is usually a change in the tracing in from twelve to twenty-four hours after the attack that is almost pathognomonic. Thus when the anterior descending ramus of the left coronary artery has been occluded and has caused acute infarction, the level of the tracing of the R-T interval is usually markedly raised in leads I and II with a rounded convexity upward, arising from the descending limb of the R-wave above the iso-electric line ("T-en dôme"); in later days, the T-wave (after two or three weeks) often becomes inverted (not always) while the R-T line may still bulge somewhat upward ("coronary T"), though it tends to approach the iso-electric level.

In some cases, the tracing may return to normal in the course of a few weeks. (For descriptions of the electrocardiograms in thromboses of other coronary branches, the special literature may be consulted.)

Too much stress should not be laid, however, solely upon inversion of the T-wave in lead III, since it is said that it may be observed sometimes in normal hearts or in hearts in which there is a relative preponderance of the right ventricle.

During the past decade attention has been paid to certain alterations in the E K that may persist for months or years after an infarction has occurred. Thus considerable importance has been attributed to the continuance of a large Q-deflection in lead III (Pardee, 1920; Wilson, 1926; France, 1934), especially when it persists in association with left axis deviation.

Emphasis has also been laid upon evidence of low voltage in all leads in old cases of coronary thrombosis by Wearn (1923), by Parkinson and Bedford (1928), and by Levine and Brown (1929). Notching, slurring, and widening of the Q-R-S complex in more than one lead has also persisted in some cases. But any of the changes just mentioned, though commonest after infarction, may also occur in cases of diffuse myocardial fibrosis without history of preceding infarction (J. Hay, 1933).

For a time it was believed that infarction may occur in certain areas of the heart muscle (especially in a girdle domain midway between the base and apex of the heart) and yet no change in the E K become demonstrable. This appears to be true for the ordinary limb leads I, II, and III. But if chest leads be used in addition to limb leads, these areas are no longer "silent" in infarction, but yield peculiar E K tracings that have been described by Wolferth and Wood (1932), and also by Katz and Kissin (1933).

In rare instances, an E K like that of acute coronary thrombosis (high take-off of S-T interval from the descending limb of the R-wave) may be met with in brief attacks of angina pectoris (Brow and Holman, 1933; Hausner and Scherf, 1933).

Treatment of Patients with Angina Pectoris and with Coronary Thrombosis

Attacks of angina pectoris (without coronary occlusion) are often promptly relieved as every practitioner knows by the use of vasodilators, say by placing a 1/100 grain tablet of nitroglycerin (of hypodermic type) under the tongue for solution, or by inhalation of the fumes of amyl nitrite (crushed pearl or ampoule), repeating the dosage if necessary until the pain disappears. Many patients who suffer from angina pectoris always carry these tablets or pearls with them so as to have them for immediate use if attacked. If a physician be present during a severe attack he may give 1/4 or 1/2 grain of morphine hypodermically. The patient nearly always immobilizes himself and certainly he should avoid all movements until the paroxysm ceases. Though theoretically epinephrin (as a coronary dilator) might be expected to stop an attack of angina pectoris, the opposite seems to be the case (Levine), perhaps because of a paradoxical reaction of the coronaries in angina pectoris.

To do as much as possible to prevent the recurrence of attacks, a thorough diagnostic study should be made of the patient and the treatment should be individualized in accord with the findings. In all cases, the precipitating causes of the attacks (excessive physical exertion; emotional excitement; sudden exposure to cold) should be sedulously avoided. The use of tobacco should be given up and the diet should be bland with avoidance of any overloading of the stomach. Gout, obesity, diabetes, or syphilis if existent should receive appropriate treatment. Cardiokinetic muscle extracts have been given, but their value remains to be determined by further observations. The periodic use of courses of purin derivatives (theobromine sodium salicylate or dimethylxanthine) or of a combination of theobromine and phenobarbital seems to be helpful to some patients. Surgical measures have been employed, including recently total thyroidectomy, but one would hesitate to recommend them as long as the condition can be made tolerable by medical measures and better management of activities.

In an attack of coronary thrombosis, the strictest physical and mental rest should be enjoined, the patient being kept continuously in bed and the use of bedpan and urinal ordered. He should have special nurses if possible who will feed him at first and will turn him over when required. For the atrocious pains, large doses of morphine—enough to control them—should be given hypodermically during the first two or three days; a quarter of a grain at a dose may be wholly insufficient and the amount necessary to give relief should unhesitatingly be injected. Later on, milder sedatives (codein, and so on) may suffice, but the physician should see to it that the patient is kept as free as possible from anxiety and restlessness and that he secures enough sleep. Heat should be applied until the period of shock has been passed. Liquid diet alone should be permitted at first; later on five feedings daily of semi-solid food and of milk may be given. A daily enema may be required to keep the intestine clear.

Though one will say only enough to the patient concerning diagnosis and prognosis to secure his co-operation in the rigid treatment, the patient's family should be told of the gravity of the condition and of the high mortality rate, even under the best of care. Even when the patient survives the first few days, the dangers are by no means passed, and bed-rest should be enjoined for 6 or 8 weeks in order: (1) To give the lesion in the myocardium the best opportunity to heal, and (2) to prevent exertions that would favor rupture of the heart or the development of a cardiac aneurysm. No digitalis should be used at first, though later in the course if signs of congestive failure develop it may be used with caution. The general practitioner who finds himself in charge of a patient with coronary thrombosis will usually do well to ask permission of the family for the aid that consultation with a specialist on diseases of the heart may give.

THYROID NOT A "BRAIN OIL"

The New York Academy of Medicine has issued a warning against indiscriminate use of thyroid extract as a tonic for tired business men. The warning, issued through the academy's Bureau of Medical Information, was inspired by a United Press dispatch from Kansas City, in which Dr. George W. Crile of Cleveland was quoted as saying, "When a deficient amount of this glandular product is secreted, and this is common in the second half of a business man's life, his brain begins to slow up and his associates notice a letting down in his work. . . . Then the man can take thyroid extract and his brain will be sharpened. . . . Thus the lagging individual can be placed back in the saddle again."

The Academy's statement, pointing out that the very symptoms mentioned might come from excessive thyroid secretion, so that they would only be aggravated by taking the pills, and warning against toying with this glandular high explosive, said:

"The crux of Dr. Crile's observations on the thyroid gland, assuming that he is quoted correctly and completely, lies in the condition which he stipulates, namely, 'when a deficient amount of this gland product is secreted.' It has long been known that the condition of inadequate secretion of thyroid called hypothyroidism or myxedema, causes

a definite slowing up of all body functions, including that of the brain. For this condition, thyroid in one form or another has been effectively prescribed.

"On the other hand, it is important that the public should be warned that thyroid is no 'brain oil' which, quantity for quantity, can increase the smooth workings of the human intellect. On the contrary, to use the same rather crude analogy, too much oil may gum up the machine.

"Fatigue, irritability and lack of the power of concentration are as liable to be the symptoms of an excessive thyroid secretion as of deficiency. The indiscriminate taking of thyroid by those who do not require it is fraught with great danger. We witness the damage that an excess of thyroid can cause in the condition clinically known as hyperthyroidism. Particularly liable to damage is the heart musculature. Medical science must regretfully warn the public that the elixir of life is not to be found in the thyroid gland."

A physician in Portland, Oregon, Dr. Junius B. Wright, celebrated his hundredth birthday in January, and when the reporters asked for something to print, he said: "Come around a year from now, and I will give you some kind of story."

PERITONITIS

CHAS. GORDON HEYD, B.A., M.D., F.A.C.S.

Professor of Clinical Surgery and Director of Surgery, New York Post-Graduate Medical School, Columbia University, New York City

"If a man knows peritonitis he knows abdominal surgery."¹

Peritonitis is, with few exceptions, a complication of some other intra-abdominal disease. It is a secondary and usually a terminal event: only with the greatest rarity is it designated as a primary peritonitis. That form of peritonitis which is due to an infection with the pneumococci is fortunately rare and because we are unable to determine the portal of entry it is sometimes, although erroneously, called a primary peritonitis. In ordinary practice peritonitis means an infective process, involving some portion of the abdominal cavity and characterized by a progressive extension and sequential involvement of various portions of the abdominal viscera.

We classify peritonitis into acute septic peritonitis and acute suppurative peritonitis according to the character of the exudate. Furthermore we speak of an acute local peritonitis and acute diffuse peritonitis according to the amount of peritoneal involvement. General peritonitis is a misnomer as the entire peritoneal cavity is seldom completely involved. Diffuse septic peritonitis is due to the streptococcus which produces little or no exudate, gives a blistered appearance to the peritoneum and produces large quantities of toxin. It has a remarkable tendency to penetrate the subserous lymph spaces with the development of sub-peritoneal cellulitis and general septicemia. The peritoneum is lusterless, thickened, edematous, markedly hyperemic or even with petechia. This type of infection occurs most frequently in women and usually arises from an uterine infection.

In the suppurative peritonitis, the condition is characterized by exudation, the formation of adhesions; the peritoneum is rough, hyperemic, thickened and plastered over with fibrinoplastic material. The bacteria most often encountered in this condition are in the order of frequency colon, streptococcus (most frequently found in women), pneumococcus

(most frequently found in women and children). By far the most frequent of the bacteria involved in the production of peritonitis is the colon group. The frequency of colon infections is of statistical importance and may not represent the true condition for the bacillus coli communis is capable of growing so rapidly that it may become predominant while the initial infection may have been caused by some other micro-organism.

The pneumococcus infection is most frequently found in children and women, and is usually associated with an upper abdominal infectious atrium, the bacteria probably coming from swallowed sputum. The pneumococcus produces a yellow-green, odorless gummy pus with flakes or masses of fibrin and a tendency to form delimiting adhesions. It is not improbable that a primary focus in the lung or ear or in the Fallopian tubes will be found on diligent search. Bacillus pyocyaneus is an uncommon cause of peritonitis but is capable of producing a very virulent peritonitis. This bacterium is a normal inhabitant of the intestine and produces green pus only in the presence of oxygen which is essential for the production of the pigment pyocin. The infection that it produces is usually a local peritonitis and this particular bacterium is never found with the colon bacillus.

The staphylococci occupy an under-terminate position in the production of peritonitis. Staphylococcus, according to Dodgeon and Sargent,¹⁵ is practically non-pathogenic; it is found on the extreme edge of peritonitic inflammation and it has been assumed that it produces a mild anticipatory inflammation of the peritoneum which is thereby a protective mechanism for creating delimiting adhesions. The staphylococcus is usually found in the early or beginning stage of chemical irritation of the peritoneum such as occurs in ruptured ectopic gestation and ovarian cyst. It produces a milk-like

Read at the Seventh Annual Graduate Fortnight of the New York Academy of Medicine, October 26, 1934

pus, non-odorous, which is usually sterile, and is essentially a reactive or protective fluid. It is this fluid that one meets when the abdomen is opened in a subacute appendicitis.

The diagnosis of peritonitis is ordinarily not difficult. A consideration of the possible primary sources of infection will in most cases lead one to a correct diagnostic interpretation; 95 per cent of all cases follow in order of frequency disease of the appendix, pelvic organs, gallbladder, and gastroduodenal zone. A history of pelvic infection, menstrual irregularity or trauma may be elicited or a history of gastric distress and the ulcer syndrome may be brought out upon inquiry. The age of the patient, the sex, the irregular dyspepsia and colic might be sufficient to confirm a diagnosis of pre-existing gallbladder disease, while the rapid and definite sequence of symptoms in acute appendicitis is characteristic and decisive.

In the early stage of a peritonitis abdominal pain is invariably present, is constant in character, and tends to be localized. It is associated with tenderness and abdominal distention. Definite abdominal rigidity is present over the area of intra-abdominal inflammation and muscle spasm is also elicited. Fever is usually present. There is a persistent, rapidly-rising pulse, with vomiting usually frequent and without effort, together with an inability to pass flatus or stool. Leukocytosis and polynucleosis ordinarily accompany the process, exceptions being found, however, in the acute fulminating streptococcic peritonitis. Early in the condition the facies is alert, and apprehensive long before the typical Hippocratic countenance becomes evident.

The total surface area of the peritoneum is about equal to the skin area, between 17,000 and 18,000 square inches.² It has been proved that absorption of fluids from the peritoneal cavity is accelerated by the Trendelenburg posture³ and minimized by the so-called Fowler posture, the rate of absorption being 15 per cent less when the head and body are elevated.

This would account for the clinical benefits observed in the Fowler, Coffey, Kuster positions. The rate of absorption varies with the different portions of the

peritoneal cavity. The most rapid absorption takes place from the diaphragm, next the omentum, thirdly the visceral peritoneum, fourthly the parietal peritoneum, and least from the pelvis. Dandy and Rowntree³ by means of phenolsulphophthalein injections into the peritoneum have demonstrated that absorption is by way of the blood vessels and irrespective of position, although the rate of absorption is facilitated by posture. Experimental and clinical data indicate that absorption is hemic, not lymphatic; that the peritoneum is capable of absorbing from 3 to 8 per cent of the body weight in one hour;² that the rate of absorption is dependent upon position; that the localization of fluid within the peritoneal cavity modifies the rate of absorption; that the character of the fluid influences the rate of absorption; that bodily respiratory and peristaltic activity influence absorption; that all absorption depends upon the living integrity of the endothelium. Solid particles are engulfed by a variety of peritoneal cells, macrophages, microphages, and the neutro-leukocytes. The great majority of foreign particles are probably encapsulated by fibrinoplastic lymph.

The absorption of soluble toxins corresponds to the absorption of fluids. Buxton and Torrey⁴ found that if a large dose of typhoid bacilli were injected into the peritoneal cavity of a rabbit the bacteria were immediately destroyed by bacteriolytic substances of the blood serum. The rapid bacteriolysis liberated a large amount of endo-toxin and an overwhelming dose of toxin was absorbed, with death. This observation is paralleled in humans by the deaths that immediately follow extensive operative procedures in the presence of an active peritoneal infection where the manipulations and trauma incident to the operation bring about an initial lethal dose of toxin. The mortality is ascribed to shock, whereas the particular cause of death is the sudden overwhelming dose of toxin.

With the patient in a recumbent position the colon forms three well defined fossae or paracolic pools: (1) the fossa formed between the transverse colon, the anterior abdominal wall and the under surface of the liver and portion of the diaphragm; (2) the lateral fossa or renal,

formed to the outer side of the cecum and ascending colon on the right side; and (3) the lateral fossa to the outer side of the descending colon and sigmoid on the left side. For the free drainage of fluid, however, from either lateral fossa into the pelvis requires an angulation of the patient from the horizontal to approximately 35 to 45 degrees. In turn, the transverse paracolic fossa is divisible into a right and left compartment by the round and falciform ligaments of the liver.

It is axiomatic that every case of peritonitis begins as a local lesion and that from this local point of infectivity there is a gradual or rapid spread of the infection to remote zones or areas of the abdominal cavity. The gastro-intestinal canal lies within the abdominal cavity in a state of hydrostatic balance and freedom of movement of the intestines is attained by the film of lymph that is at all times present on any peritoneal surface. Since most cases of peritonitis are secondary to acute perforating appendicitis and then in the order of frequency secondary to pelvic affections, gallbladder infections, and perforations of the gastro-duodenal zone, it is well to consider the mechanism of the typical case of peritonitis.

The picture as it occurs from acute perforation of the gastro-duodenal zone is not typical of the ordinary type of peritonitis. The pouring forth of gastric or duodenal contents from a perforation brings about an abdominal response characterized by abdominal rigidity that is equalled by no other intra-abdominal condition.⁶ The acute onset, board-like rigidity, complete immobilization of the patient, the early initiatory symptoms of shock, is a picture portraying all the evidence of a serious condition. The approach to the serosa of an infective agent is characterized by a throwing out by the adjacent endothelial cells first of a transudate and later an exudate. This yellowish fibrinoplastic fluid is the response by the peritoneum to a bacterial or chemical irritation. The coils of small intestine or large intestine in the immediate vicinity of the infection become first hyperactive and later parietic with the formation of adhesions. This mechanism is essentially protective in that it seeks to wall off or to throw up barricades against the spread of infection. It is in this stage that most

of the cases of peritonitis are seen by the attending surgeon.

From these initiatory pathological changes there begins a progression of events that are represented in the following sequence: (a) an increase in the severity of the pathological reaction; (b) further attempts to arrest the spread of the infectious process by walling off; (c) a breaking through of the barriers of the local peritonitis and the development of a progressive spreading, diffuse peritonitis. Infection is spread within the abdominal cavity largely by movements of the small intestines, the alternate rising and falling of the diaphragm creating a pump-like or siphonage current.

Death occurs in peritonitis from (a) toxemia—the result of peritoneal absorption; (b) intestinal obstruction, either in the form of adynamic ileus, or a dynamic ileus (Handley Sampson⁶ is of the opinion that absorption of the entero-genic toxins above the obstruction are really the death-producing factor); (c) septicemia, and (d) the complications—pulmonary, cardiac, exhaustion, and pyemia.

The clinical consideration of peritonitis embraces three phases: (1) diagnosis and preoperative treatment; (2) the operative treatment, and (3) the post-operative treatment. The severity of the condition is directly proportional to the amount of absorption from the peritoneum and the treatment resolves itself into measures directed toward modifying the degree of absorption and to correct intestinal obstruction when and if it intervenes. The outstanding surgical or medical considerations are: to keep the peritonitis local; to prevent its becoming spreading or general in type; to bring a spreading peritonitis into a condition of local peritonitis.

Surgical intervention in peritonitis has gone through many phases in its evolution, from the earlier days of doing nothing to a second phase when the therapy consisted of a laparotomy with aspiration and lavage of the entire intra-abdominal cavity. A third phase considered the physiology of peristaltic rest and peritoneal absorption and consisted of rest and starvation,⁷ plus adequate and timely surgical intervention.

By far the most active agent in changing a local peritonitis into one of the spreading character is the use of

cathartics or laxatives in the presence of abdominal pain. If one should select any rule for guidance in the case of suspected peritonitis it would be "obtain and promote peristaltic rest." By peristaltic rest is meant the more or less complete cessation of peristaltic movement of the intestine. By far the simplest way to obtain peristaltic rest is to prevent absolutely the taking of anything by mouth. This applies with particular force against the taking of any food, even water, and the absolute withholding of any laxative or any cathartic.

The effect of food, or even water, taken into the stomach is to stimulate intestinal peristalsis and a segment of small intestine that may be quietly wrapped around a diseased area in the neighborhood of a perforated appendix is by the very movement of peristalsis spread and moved to some other non-infected area of the abdomen. The result is the spreading of an infection over the omentum, along the mesentery and from coil to coil of intestine. If this mechanism obtains upon the taking of only food products and water, how much more magnified is the peristaltic movement induced by salts, laxatives, or castor oil.

It has been found that an icebag applied to the abdomen tends to inhibit peristalsis whereas the hotwater bottle tends to stimulate peristalsis. Furthermore, the application of an icebag to the abdomen brings subjective relief but tends to prevent the local hyperleukocytosis essential for protection. Fauntleroy¹⁸ has demonstrated that cases of acute appendicitis treated with icebags show a general leukocytic count of about 4,000 per cubic millimeter less than those cases that were not treated. It has been found that a quarter of a grain of morphine is an effective antiperistaltic, producing almost complete cessation of intestinal movement anywhere from four to six hours.

After a certain number of coils of intestine have become inflamed or infected there develops what is the single, most outstanding death-producing factor in peritonitis—the development of intestinal obstruction. There is ordinarily a varying degree of abdominal distention but in the protective mechanism resorted to by the peritoneum to prevent the extension of the inflammatory process coils of

intestine become acutely angulated, bound down to one another and mechanical obstruction ensues.

It was early discovered that the rate of absorption varied with different localities within the abdomen and it has been an observation since time began that pelvic infections other than the parametrial infections of the puerperium were ordinarily not lethal. With some degree of assurance it was assumed that the higher the infection within the abdomen the more rapid the peritonitis and the greater the mortality. Hence, it was assumed that the rate of absorption from a peritoneal cavity could be influenced by the posture.

At the turn of the century Clark⁸ suggested that the foot of the bed be elevated so that absorption could be accelerated and the patient thus enabled to throw off the toxemia more quickly. Experience demonstrated that the absorption from a peritoneum in the Trendelenburg position was much more lethal than when the absorption was diminished.

It remained for Russell Fowler in 1906⁹ to advise the reverse position that now bears his name, the so-called Fowler position. It was assumed by elevating the patient so that the head was at least from 35 to 45 degrees elevated from the horizontal that absorption would be less rapid and therefore the patients would ward off or protect themselves from a too rapid or lethal inundation of the circulation with the toxins. Experience demonstrated that this was a protective measure and the Fowler position for peritoneal infections is now almost universally applied in the treatment of peritonitis.

The next step in chronological sequence in the treatment of peritonitis was contributed by a number of observers but given official status by Ochsner⁷ who suggested that in a case suspected of having peritonitis there should be absolutely nothing given by mouth, and that the patient should be maintained in the Fowler position, and the so-called rest and starvation treatment instituted. The acceptance of this rational form of therapy produced results yet the mortality remained excessively high by reason of the inability of the rest and starvation method to prevent the development of the more seriously complicating factor, viz., the mechanical obstruction of the bowels.

Murphy "revolutionized the whole treatment of peritonitis."¹⁰ In a paper read before the British Medical Association at Toronto in 1906, and which today is still a classic of surgical pathology and surgical thinking he added two noteworthy additions to the treatment of peritonitis. The first—institute surgical drainage—"get in quick and get out quicker," and secondly, the maintenance of water balance by proctoclysis.

The ancient Hippocratic dictum, *ubi pus ibi evacuo*, was one of the salient points of the Murphy idea. The presence of pus is lethal when the products of an infection are retained under pressure and the precise and quick and accurate method of relieving pus pressure is by the institution of surgical drainage. It is by no means necessary that the pathological organ should be removed, or that the entire pathological zone should be subjected to surgical exposure. Surgical intervention in peritonitis rests upon the simple procedure of instituting drainage to the site of the infection and to the relief of intestinal obstruction. No lavage or "wiping away" of lymph or undue handling of intestines should be attempted. If the patient is to receive nothing by mouth, it becomes necessary to maintain an adequate degree of water in the tissues and in the circulation.

It is quite obvious that with the lack of water by mouth and the increased loss of water by fever and vomiting there results increased concentration of the toxins in the blood. This in turn will destroy the eliminative function of the kidneys.

Murphy suggested that the rectum and colon could be utilized for the absorption of fluid and he recommended the giving by rectum after the drop method of huge quantities of normal saline, up to five or even more quarts of water per day.

It was found that the rectum not only tolerated the introduction of fluids but that the absorption was so rapid that it became possible to so load the vascular system with water as to produce an hydremia. The first beneficial effect would be to dilute the toxins already present in the circulation. In the second place a further therapeutic effect was obtained in that it was possible to reverse the peritoneal current and to actually

cause the peritoneum to be a secreting membrane instead of an absorbing membrane.

The clinical fact that peritoneal cases with intra-abdominal drainage can take more fluid by rectum than cases without drainage would seem to lend confirmation to this. It was readily apparent that the taking of so much salt was, per se, dangerous, and it was observed that edema over the shins occasionally occurred and infrequently an edema of the lungs with hydrothorax resulted from a too great an intake of salt. Accordingly, the normal saline for proctoclysis was replaced by ordinary tap water, especially after Trout¹¹ had demonstrated that plain water was more readily absorbed, was better tolerated in the rectum and the patient required less water to satisfy thirst after proctoclysis was discontinued than when saline was employed.

The experimental study of Christian on artificial nephritis and the danger of salt retention in nephritis, together with edema of the ankles, face and lungs with proctoclysis with saline solution demonstrated that the amount of salt by proctoclysis is a factor of danger.

Further additions to the treatment of peritonitis came from the field of chemistry and were evolved from a study of the physiological functions of the liver. It may be said in all seriousness that the protection of an individual from abdominal infection and abdominal surgery is dependent upon the liver being adequate to function in a normal capacity in the presence of abnormal absorption. The great rôle of sugar—dextrose—in protecting body proteins, in allowing for the more adequate and more ample function of liver, became apparent; hence various strengths of dextrose solutions were added to the fluid to be given by rectum.

Human life may be said to depend upon an adequate and precise adjustment of the water-salt balance. Rowntree¹² states that the total of all secretions poured into the intestinal tract varies from 7,500 to 10,000 c.c., an amount of fluid more than twice the total blood volume. Orr¹³ has succinctly demonstrated the outstanding importance of dehydration, hypochloremia and acid-base balance in preoperative and postoperative treatment, and indicates that while an animal may lose 40 per cent of

its body weight in glycogen, fat, and protein without death, a water loss of 10 per cent is associated with serious complication, while a loss of 20 to 22 per cent of water invariably brings about death.

Peritonitis with its repeated and effortless vomiting brings about a marked loss in blood chlorides—hypochloremia. The indication is to provide a proper amount of chlorides, by the introduction of 200 to 500 c.c. of a 2 to 4 per cent solution of sodium chloride intravenously, or if a more rapidly acting salt therapy seems necessary 20 c.c. of 10 per cent solution of sodium chloride intravenously.¹⁴ If vomiting occurs, either before or after operation, complete and absolute deflation of the stomach is accomplished by introducing an indwelling nasal Levine tube.

We may therefore summarize the treatment of peritonitis (see Table) as follows: (1) an accurate anatomical diagnosis of the site and origin of the infection; (2) adequate measures to restrict the infection to a local manifestation and to prevent the extension to a general peritonitis; (3) early surgical intervention; (4) absolutely nothing by mouth; (5) the Fowler position, either by angulation of the patient or by angulation of the bed; (6) the maintenance of adequate water balance—minimal of 3,000 c.c. daily over and above the amount lost by vomiting or Levine tube drainage—(a) by proctoclysis, (b) by hypodermoclysis, (c) by phleboclysis; (7) an adequate maintenance of dextrose intake—(a) by rectum: solutions containing 4 to 10 per cent dextrose, (b) by intravenous method: from 4 to 10 per cent solutions of normal saline when volumes of 800 to 1,000 c.c.

are given; from 20 to 40 c.c. of 50 per cent dextrose solutions when only dextrose is given; (8) the use of the Levine tube intranasally for complete emptying of the stomach; (9) in the presence of vomiting and to counteract hypochloremia and alkalosis, the giving intravenously of hypertonic saline solutions, 2 to 4 per cent in quantities of 200 to 500 c.c., or with 10 c.c. of 2 per cent solution of sterile calcium chloride; (10) physiological rest of the cerebrospinal nervous system by morphine or its derivatives, after the diagnosis has been made and laparotomy performed.

TABULATION OF TREATMENT OF PERITONITIS

Preoperative — operative — postoperative

1. Nothing by mouth—Ochsner "Rest and Starvation."
2. Gastric drainage—indwelling nasal Levine tube.
3. Fowler position.
 - (a) Angulation of bed, 35°.
 - (b) Angulation of patient.
4. Morphine for pain or restlessness.
5. Prevent dehydration—amount lost by stomach + 3000 c.c.
 - Proctoclysis, Murphy.
 - Tap water + 10 per cent glucose.
 - Hypodermoclysis.
 - N/10 Saline.
 - Phleboclysis.
 - N/10 saline + 10 per cent glucose.
6. Prevent hypochloremia and alkalosis.
 - Replace fluids and chlorides lost in vomitus.
 - Intravenous method.
 - 2–4 per cent hypertonic saline.
 - 10 c.c. 2 per cent solution calcium chloride.
7. Surgical intervention.
 - Early operation for primary focus, with drainage.
 - Operations for intestinal obstruction.

NEWER METHODS OF TREATING PEPTIC ULCER, CONSTIPATION, AND INDIGESTION

GEORGE CRILE, M.D.

CLEVELAND CLINIC, CLEVELAND, OHIO

Twenty-four years ago in an Ether Day address at the Massachusetts General Hospital, I enunciated certain principles which have ever since found their application in the Cleveland Clinic in the development of certain methods of treatment and prevention of those diseases in particular which by virtue of their origin and nature we have termed kinetic diseases. Twenty years ago I performed the first of a series of operations in which adrenalectomy was either performed alone, or was combined with sympathectomy or with thyroidectomy or with both, for the purpose of lessening the "kinetic drive" to which these diseases are due. Later we not only added peptic ulcer to the list of the kinetic diseases but found that constipation and indigestion might be due to the same kinetic causes, and we found also that bilateral denervation of the adrenal glands gave more permanent results than adrenalectomy because of the tendency of the remaining adrenal to compensation. Recently we have found that unilateral denervation with division of the greater splanchnic nerve is as effective as bilateral denervation in many cases.

We shall cite certain case histories which offer evidence in support of our assumption both that peptic ulcer, chronic indigestion, and constipation may justly be termed "kinetic diseases" since they are due to pathologic physiology of the energy system, and that these conditions are ameliorated or cured by adrenal denervation, but first I shall discuss the rationale of this procedure in such cases.

That the psychic factor exercises a powerful control, not only of the gastric secretion but also of the entire digestive tract and digestive processes, is a matter of common experience, and that the adrenal glands are concerned in the production of these disturbances has been abundantly proved by the investigations of Cannon and others.

This power of the adrenal glands over

the gastro-intestinal tract would appear at first sight to make all animals above the level of the reptiles equally liable to peptic ulcer, to indigestion, to constipation. Yet we know that this is not the case for wild animals do not have peptic ulcer nor indigestion and even among humans, peptic ulcer and indigestion occur rarely in primitive man and are found most commonly among teachers, lawyers, physicians, clergymen, business executives, diplomats, and that large group in other walks in life that are worried and have many anxieties, have indigestion, are constipated. Among the different races those of a nervous, high-strung disposition are more liable to have digestive disturbances than are those of a more phlegmatic type. Thus peptic ulcer occurs more commonly in the Jewish and Latin races than in the Nordic races.

Where is the cause of this difference to be found? Anatomically it would seem that all animals and all humans possess alike an adrenal-sympathetic system, and that just as the heart performs the same function in each, the adrenal-sympathetic system should function alike in each with identical results. By such reasoning we are leaving out of account two other essential units of the energy system of man and animals, the brain and the thyroid gland. Let us study for a few moments the comparative anatomy of this energy system.

From the point of view of their control of energy we may consider the animal kingdom as divided into three groups, although of course no absolute grouping is possible as there must be an overlapping for some animals have characteristics which pertain to each of two of the proposed groups.

1. The first, which we call the protected groups, includes animals whose safety depends upon chemical or mechanical devices such as carapaces, quills, poisons, odors, or upon concealment, such as the armadillo, skunk, porcupine, alligator. These

Read before the Rochester Academy of Medicine, Rochester, New York, November 1, 1934

animals require for safety but little expenditure of energy, and therefore the whole energy equipment is relatively small.

2. The second group, which we call the pure energy group, includes animals whose survival depends upon the expenditure of energy in attack or escape such as the lion, fox, antelope, squirrel.

3. The third, the strategy group, includes those animals which depend mainly for survival upon the direction of energy by a controlling brain.

In animals in the second or pure energy group the adrenals are larger and the adrenal sympathetic system is more complex than in either of the other groups. In the protected group not only are all the units of the energy system relatively small but the adrenal sympathetic system is exceedingly simple in its connections. In both the pure energy and the protected groups the adrenal glands are larger than the thyroid gland; in man the thyroid gland is larger than the adrenal glands and in both these groups the adrenal sympathetic system is complex and more so in the pure energy group than in the strategy group. In a fox and squirrel, for example, the weights of the adrenal glands were respectively $3\frac{1}{2}$ and $7\frac{1}{3}$ times larger than the thyroid gland, while in man the thyroid gland weighs approximately twice as much as the adrenal glands.

The thyroid gland maintains the level of activity of the brain and its size therefore depends upon the rate and constancy of demands for energy production. The thyroid gland, therefore, has reached its highest development in man in whom the demands for energy are ceaseless. The size of the adrenal glands and the complexity of the adrenal sympathetic system depends upon the need for the sudden use of energy in attack or escape. This system has therefore reached its highest development in animals like the lion and tiger, in which there is need for sudden and fierce attack in securing prey, while between the times of attack or escape there is little need for energy as the time is spent in eating and sleeping.

In what way can these facts contribute to a better understanding of peptic ulcer?

The specific action of the adrenal sympathetic system as we have stated is

to inhibit every organ and tissue that is needed for the great muscular activity of the attack or escape. Among the organs most affected therefore are those of the digestive system.

Thousands of years ago in the ancestor of present-day man, we may believe that since his safety depended principally upon muscular attack and escape, the adrenal glands might well have been larger than the thyroid gland. Primitive man attacked, secured his food, escaped to the trees and slept. As the ancestors of man came out of the trees, however, as his hands guided by the developing brain developed new methods of sustenance by tilling the soil and domesticating animals; as the developing brain showed the advantages of co-operation with his neighbors, in times of stress and fear his adrenal sympathetic system still continued to act as if active physical struggle was required, and therefore the gastro-intestinal tract was inhibited. The physical activities of attack and escape remain among man's racial memories and although the highly developed brain of civilized man has devised religions, laws, customs and systems of education, yet it can not eradicate the racial memories which are woven in the protoplasmic net of inheritance. It follows that the mechanism by which motor acts are performed and the mechanism by which emotions are expressed are one and the same.

Civilized man is subjected to innumerable actions but much restraint. The more highly civilized the man is, the greater in number are the exciting stimuli, the greater the restraint.

Because of our complicated life, we have many fears—fear of the loss of money and property, fear of moral disgrace, fears as to social status and as to health. Man is beset by fears because of his memory mechanism, a mechanism that has made possible social and economic co-operation. This delicately poised social and economic relation is under constant strain. The driving force of fear and of its lesser form, worry, stimulates human beings to strivings, competitions, rivalries, and jealousies. The greatest and the most constant fear of man is fear of his fellow man. In the world of fears, worries, and anxieties, in which civilized man is engulfed, he fears just as the

lower animals fear, largely in the physical terms of his ancestral fight or flight. In consequence, the racial action patterns tyrannize over the remainder of the organism, especially in those individuals who have developed their brains to the greatest degree.

Initiation of action is the function of the special senses and of memory. Although there may be no physical danger, yet, upon receiving an adequate stimulus, racial action patterns throw the switches for full steam ahead, activating the muscles, the adrenals, the thyroid, the heart, the metabolism and the respiration, inhibiting simultaneously the digestive and procreative systems, and as the result of these repeated inhibitions, among other results indigestion, peptic ulcer and constipation may result. The incidence of peptic ulcer to which we have already referred is evidence of the validity of this reasoning. Other ulcers are constant; peptic ulcer appears in rhythms. Peptic ulcer has not only a rhythm related to the span of life, appearing more commonly in the active young adult period, but it also has a rhythm related to seasons of the year as it appears more often in the spring and autumn. It occurs more frequently in males, the incidence as compared to that in females being as seven to one. Peptic ulcer not only favors the human race and its most advanced members, it not only chooses for its incidence spring and autumn, and the active period of life, but it is selective even in its victims, as its periods of activity correspond with periods of work, worry, and fatigue.

Peptic ulcer, indigestion, and constipation are aggravated by influences that cause an increase of activity of the sympathetic nervous system such as emotion and focal infection, and is mitigated by influences that lessen the activity of the sympathetic system such as relaxation and holidays. Peptic ulcer is mitigated by any diet or medication that diminishes or neutralizes the acidity and stabilizes the motility of the stomach.

From these considerations it is clear that peptic ulcer itself is an end result; that it is a symptom, and not a separate disease. It is an example of pathologic physiology, not of pathologic anatomy, and the energy or kinetic system of man

is the mechanism which is involved in the pathologic physiology which produces a peptic ulcer.

It remains to consider how an ulcer of the stomach is established and maintained in the man in whom there is an overstimulation of the kinetic system.

Edward Martin and Carlson have shown that the most probable mechanism is the production of a sphincterismus at the pylorus by changes in the activity of certain components of the autonomic nervous system. This sphincterismus causes a break in the perfectly balanced mechanism at the pylorus whereby a balanced acid-alkali relationship is established and the gastric juice, being thus deprived of the alkaline duodenal fluid, rises in acidity and coincidentally the motility of the stomach is greatly increased.

Manifestations of increased activity of the sympathetic nervous system are frequently noted in cases of peptic ulcer, such as increased perspiration, increased nervousness, a tendency to tachycardia, excessive motility, tenseness, excitability, short temper; in other words, many of the general symptoms of mild hyperthyroidism and of mild neurocirculatory asthenia.

Another interesting and significant fact is that the incidence of digestive disturbances in hyperthyroidism is higher than in the normal population. Furthermore, to the high-strung, high-capacity victims of peptic ulcer, as to those suffering from hyperthyroidism or neurocirculatory asthenia, a holiday affords almost a specific relief. These considerations would seem to strengthen the hyperkinetic or neurogenic theory regarding the etiology of peptic ulcer.

If peptic ulcer is not a morphologic pathology due to exclusively local causes, but, on the contrary, is due to an excessive drive of the sympathetic system, then the administration of a drug, that would counteract the excessive action of the components of the autonomic system, would mitigate the pathologic physiology, namely, the spastic contraction at the pylorus, and relieve the symptoms. This is an established fact.

The seven biologic excitants of the adrenal-sympathetic system are pain, emotion, infection (foreign proteins),

hemorrhage, asphyxia (inhalation anesthesia), thyroid hormone, and adrenaline. If the kinetic theory as to the causation of peptic ulcer is true, then emotional excitation, infection, pain, thyroid hormone, need be the only biologic excitants to be discussed in a clinical sense. Pain certainly aggravates a peptic ulcer. Emotion and physical exertion are closely related. Both aggravate peptic ulcer, and equally do the toxins of infection. This leaves the thyroid hormone to be discussed. The most outstanding physiologic action of the thyroid hormone is to step up the activity of the brain and the adrenal-sympathetic system, hence emotionalism, hence digestive disturbances. This factor, we believe, is clearly related to peptic ulcer, as we have noted 58 cases in which peptic ulcer has been associated with hyperthyroidism. In these cases thyroidectomy has been followed by a cure not only of the hyperthyroidism but also of the ulcer. Doubtless there were many undetected cases of peptic ulcer among our cases of hyperthyroidism, as x-ray examinations would have revealed, for in hyperthyroidism digestive disturbances of every kind occur frequently and are taken for granted.

The above considerations offer the clue to the physiologic plan of management. The details vary with the personal equation and the inclination of the physician, and equally those of the patient. In many instances peptic ulcer can be rationalized out of existence. Happily, peptic ulcer passes by the more completely rationalized and controlled men and women who are occupying front line positions in civilization's forward march.

So much for the etiology of peptic ulcer and other digestive disturbances. In view of this etiology, what line of treatment is suggested?

The chemical damage due to the accumulation of the injuring gastric juice may be prevented by drawing off the highly acidulated gastric juice by a tube; equally is it prevented by emesis, by lavage, or by alkalis.

The sphincterismus may be relieved by demobilizing the kinetic drive of the brain by a holiday, by apoplexy, by softening of the brain, or by senility.

Although pyloroplasty and gastro-

enterostomy, or alkalis, are followed by immediate relief, the patient still is in full possession of the pathologic physiology, which continues to work on its original plan—continues to exercise its pathologic action. For a time after pyloroplasty or gastro-enterostomy, the local sympathetic mechanism at the pylorus, as the result of an activation of which a peptic ulcer was produced, is not reconstructed; but, in time, after either a pyloroplasty or a gastro-enterostomy, the innervation is reconstructed, and, in certain and altogether too many cases, the continuous excessive drive re-establishes the pathologic physiology and the ulcer. This we call a recurrence, but it is a recurrence strictly and only of the ulcer. The pathologic physiology remains unchanged from the first.

This is not equally true of resection of the stomach, for this procedure so extensively destroys the stomach, that the pathologic drive is unable to fabricate an excess amount of ulcer-producing hydrochloric acid and pepsin.

The cases we have been considering are the active ulcers, which usually occur in younger subjects or in the hyperkinetic types of men. The picture is different in individuals of an older, more quiet temperament, and especially in patients in whom obstruction at the pylorus is present. These are mostly cases of healed ulcers. The surgeon in fact operates to relieve the serious complication of a healed, or at least an inactive, ulcer. On the fine results in such cases, much of the good repute of the surgical treatment of ulcer rests.

This brings us to the consideration of an operation devised for the purpose of changing the mechanism whereby the pathologic physiology is produced, an operation performed at a vulnerable point in the adrenal-sympathetic system.

If, as we have argued, this unique disease is due to a long-sustained overactivity of the adrenal-sympathetic system, then a surgical interference with this system should afford a measure of immediate relief and in a period of time a steady improvement, such as follows thyroidectomy in a case of hyperthyroidism.

When there is obstruction at the

pylorus, we may assume that a healed or at least an inactive ulcer exists. In this case almost ideal results are secured by a simple gastro-enterostomy. When there is an active non-obstructive ulcer in an active, young, high-strung, worrying individual, then gastro-enterostomy is not indicated, because of the tendency to the formation of recurrent ulcers. Recurrences are more resistant to treatment than is the primary ulcer. The last estate is worse than the first. In the case of a recurrent, intractable ulcer in a young individual with a high-strung, worrying temperament, we seek to change the pathologic physiology by denervation of the adrenal glands, otherwise gastric resection is the operation of choice. This procedure is comparable to that employed by Dr. W. M. Scott in surgery of the sympathetic nerves for the relief of mega-colon.

The following case histories illustrate the effects of denervation of the adrenal glands upon chronic indigestion and upon intractable peptic ulcer.

CASE I. The patient, a woman 30 years of age, was first seen on July 22, 1931. She presented typical symptoms of neuro-circulatory asthenia; namely, cold, moist hands, a pulse rate ranging between 80 and 100 and nervousness. There was a diffuse enlargement of the thyroid gland. The basal metabolic rate was minus 3 per cent. The patient suffered from indigestion and was constipated so that she took cathartics daily. She had a poor appetite.

Adrenal denervations were performed on July 24 and 31, 1931. Gastric analysis before and after the second denervation gave the results as seen in Table I.

PROGRESS NOTES

Three months after the denervations the patient wrote: "About the second week I began to feel so much better I could hardly realize it. That terrible feeling like I

must weep over everything left me. I wasn't nervous and *my stomach got so much better than I could eat almost everything and had an appetite. I mean things had a better taste.* I can't remember of any time when food tasted so good as it did to me then and didn't bother me. My heart began to slow down also."

After the good time referred to in this letter the patient went to California. The preparation for the trip and the traveling proved to be too much for her and some of the good effects described above were overcome but only temporarily, for three months later, six months after the denervations, the patient wrote: "*My nerves and stomach are fine, especially my stomach. I feel like I have a new one.*"

In January, 1933, one and one-half years after the denervations she writes: "My stomach is still good. It is something I can hardly realize how it could be changed so quickly." The patient was last heard from in June, 1934, nearly three years after the denervations. In this letter although she complains of some subjective symptoms, she adds in a postscript, "To be able to eat is a wonderful thing, although I'm getting used to it now."

Comment

In this patient the indigestion and constipation entirely disappeared promptly after the denervations. This patient continued to complain of some subjective symptoms but always writes positively regarding her excellent digestion—sure proof that her recovery in this respect was complete.

CASE II. The patient, a man 52 years of age, was first seen March 23, 1933. He complained of severe abdominal pain, loss of weight and of appetite, and nervousness. Four months before we saw him he had experienced a sudden attack of severe boring epigastric pain. This was followed by repeated vomiting of recently ingested food. He was sick in bed for three weeks. Since that time he had noted increasing nervousness, tremor of the hands, irrita-

	25	47	62	55	68	Free acid
Six days after second denervation.....	16	24	41	52	55	Total acid
	0	12	30	36	34	Free acid

bility, tachycardia and palpitation and he lost 13 pounds in weight. He continued to have almost daily attacks of abdominal pain which came on three to five hours after eating and were always relieved by food.

He had always been highstrung and hyperkinetic. His business, that of a sales director, required constant action and quickness of thought. He was interested in art and especially in the theatre. He had been a good student but not at the head of his class.

The temperature was 99°F.; pulse rate, 138; blood pressure, 140/92; basal metabolic rate, plus 9 per cent. The thyroid gland showed a symmetrical bilateral enlargement. The eyes were slightly prominent but there was no lidlag and no hippus; there was a fine rapid tremor of the hands. There was no epigastric tenderness but x-ray examination revealed an ulcer on the posterior wall of the duodenal bulb and also a diverticulum on the lateral wall of the second portion of the duodenum at the tip of which there appeared to be another ulcer. The stomach was hypertonic and showed hypermotility, being completely empty in three hours.

In spite of the normal metabolic rate it was obvious that the patient had an active hyperthyroidism. A duodenal ulcer was performed on five days later by a denervation of the left adrenal.

PROGRESS NOTES

For the first six days after the denervation the patient suffered from abdominal pain which was relieved by alkalies. He was kept on a Sippy diet during this time as during the preoperative period. Beginning with the seventh day the patient experienced no abdominal discomfort whatever and could eat anything although he complained of lack of appetite and aversion to food. The second month Sippy diet was prescribed without alkaline powders and the patient was sent home to return a month later for the second denervation. When he left the hospital his pulse rate was 72. The pathological report on the thyroid tissue that was removed was

colloid goiter with multiple adenomata.

He had absolutely no stomach distress and no indigestion. There were no objective signs of nervousness and the patient said that he felt calm and at ease. There were no tremors.

Gastric analyses made before and nine days after the denervation gave the findings as reported in Table II.

One month after the denervation the patient wrote that he was working part of each day and he adds "am doing splendidly." He was seen shortly after the date of this letter when he came to the clinic for observation. His pulse rate was 84. He had absolutely no stomach distress and no indigestion. There were no objective signs of nervousness and the patient said that he felt calm and at ease. There were no tremors.

Two months later the patient was seen again. He had been taking a modified Sippy diet. He had continued to gain weight and had felt well until 3 days before we saw him when he had an attack of nausea and vomiting with rather light colored stools. An x-ray examination showed a normal duodenal bulb and an apparently smaller diverticulum but there was still hypermotility of the gastrointestinal tract.

Six months after the denervation the patient was still following the modified Sippy diet but still had some distress. For a few days before we saw him he had taken only milk and cream with some relief. During these six months the patient had taken no alkaline powders. An x-ray examination at this time showed a slight deformity of the duodenum which was believed to be a healed ulcer.

Thirteen months after the denervation the patient wrote as follows: "I am pleased to report that my progress has been so satisfactory that I have failed in my expectation to see you more frequently. Have gained weight continuously and am free from the rapid pulse and extreme nervousness that prevailed before the thyroidectomy."

The patient was last seen in July, 1934, fifteen months after the denervations. He was having no physical trouble of any kind

	19	9	6	0	0	Free acid

and was eating practically everything. He had gained 30 pounds in weight since his operation.

Comment

This may be classified as a 100 per cent cure. Both the hyperthyroidism and the peptic ulcer disappeared after the dekineticizing procedures.

CASE III. The patient, a man, 42 years of age, was first seen June 16, 1932. The patient had first noted pain in the epigastrium when the stomach was empty following an operation for acute appendicitis in 1922. The patient continued to have attacks of pain at frequent intervals, rarely being symptom-free. The pain was sharp and burning in character; occurred one and one-half hours after eating; was partially relieved by milk or other food and alkalies; awakened him at night and was worse when he was worried or fatigued. He had tried a modified Sippy diet, alkalies and rest, but these measures merely mitigated but did not entirely relieve the pain.

Seven years before we saw him the patient had a perforated duodenal ulcer, located just distal to the pylorus. This had been treated by inversion and closure without any resultant relief. One year before there was again a perforated duodenal ulcer which was treated by closure and a posterior gastro-enterostomy without any relief, and two months later the patient had hemorrhages indicated by tarry stools.

Nine months before we saw him the pains became so severe that the patient had to quit his work. He went to bed and took a strict Sippy diet with alkaline powders without relief. In the following month an x-ray examination showed a jejunal ulcer one inch from the stoma, which was functioning well. The stomach and jejunum were spastic and there was a deformity of the duodenal bulb.

Three months before we saw him another x-ray examination again showed the jejunal ulcer; the barium escaped through the pylorus and the enterostomy opening; the stomach and intestines were hypertonic; the colon was spastic. The pains were so severe that the patient was unable to work.

The patient was a nervous individual of New England stock—very alert, active, conscientious, and aggressive. The temperature was 98.2°F.; pulse rate, 78; blood pressure, 124/74; basal metabolic rate, plus 5 per cent. Abdominal examination showed diastasis of the upper recti with a ventral hernia. An x-ray examination revealed a "diverticulum or old accessory pocket from

a healed jejunal ulcer just beyond the gastro-enterostomy which functions well; hypermotility, most of barium being in right colon in three hours. Deformed duodenal bulb probably from healed ulcer. Barium passes rapidly through both pylorus and gastro-enterostomy."

Denervations of the adrenals were performed on July 5 and 13, 1932.

PROGRESS NOTES

When admitted to the hospital, the patient was following a rigid Sippy diet, taking milk and cream every two hours. Following the first operation he asked for an increase in diet as his ulcer pains had disappeared. At the time of his discharge from the hospital he was on a liberal diet and had no discomfort.

Two months after the denervations the patient wrote as follows: "My health seems to be improving steadily. For some time now I have been at the stage where I am unaware most of the day that I have a stomach. Occasionally I am reminded of it along toward evening but I find myself sleeping through the night quite regularly. I am back at work and am standing the gaff very well."

He was seen in December, 1932, five months after the denervations. He said he felt "infinitely better." He was practically symptom-free.

Seven months later he wrote: "It is interesting to reflect that this year, for the first time in three years, I did not spend the Fourth of July in the hospital. A year ago this time I was just about leaving your hospital. This year I spent the Fourth at a house-party in the Adirondacks and, with certain trifling exceptions, did what everybody else did."

The patient was last heard from in May, 1934, nearly two years after the denervations. At this time he wrote as follows: "I have for months now rarely had occasion to think of my health. Thanks to you it has become automatic. Yet I am not a model patient because I now smoke considerably and take a drink now and then. The symptoms which formerly troubled me have long since disappeared."

Comment

This is a 100 per cent cure in a case of intractable jejunal ulcer in which repeated operations had been of no avail. Unfortunately no postoperative x-ray examination was made but none is necessary for the clinical results speak for themselves.

2020 EAST 93RD STREET

THE PSYCHIATRIC POINT OF VIEW

BERNARD GLUECK, M.D.

OSSINING-ON-HUDSON

I

That individuals differ very markedly in their reaction to disease is well known, and often enough the physician feels highly rewarded when he has succeeded in converting a situation in which the disease has the patient, so to speak, to one in which the patient has the disease.

Such a victory is always highly significant, but it is especially so in those patients in whom a transient or more protracted somatic disorder attaches itself to an already existing disturbed equilibrium of the personality as a whole. The advent of the somatic disease furnishes under such circumstances a long-sought-for opportunity for a regression to infantile modes of reaction and for an exploitation of a real illness in the service of needs which relate to long-standing problems in the personality's total adjustment to the requirements of living. It is the great merit of present-day psychopathology and particularly, the psychoanalytic contributions to it, to have pointed out the inadequacy of the viewpoint that life adaptations have to do solely with environmental and accidental vicissitudes of human living. A more accurate evaluation is now possible of the great significance for the destiny of the individual of the internal, subjective world of impulse and striving as determinants of attitude and action. Disease, as an individual experience, whether mainly somatic or mainly psychological in its manifestations, is profoundly affected in its origin, course, and outcome by these subjective elements of the personality, since they more than anything else determine the personality's reaction to the event "disease."

The following case is illustrative of what we have in mind and is typical of a class of patients which is being encountered with much greater frequency than heretofore, owing to the improved co-operation between the general practitioner and the psychiatrist.

The patient, who was admitted to Stony Lodge on October 25, 1934, is an

unmarried white female, aged 40, who for the past two years has been more or less totally incapacitated because of a variety of gastrointestinal complaints for which a most searching investigation reveals no somatic pathology adequate to account for the patient's symptoms. On the other hand, the total-personality reactions of the patient, in attitude, speech, and behavior indicate clearly a marked regressive tendency to infantile modes of reaction; a clearly demonstrable wish to be ill, and tendency to an egocentric exploitation of her symptoms; a deeply rooted "attention getting" habitus and drive, and consequent resistance to cure, as well as a negation of positive signs of improvement.

The disorder began about two years ago, presumably with an attack of intestinal influenza and has been in the main progressive ever since, and chiefly characterized by complaints of severe epigastric pains upon intake of food, general weakness, particularly of legs, flickering in front of her eyes, spasmodic, painful contractions of the right upper quadrant of the abdomen, extending to the back, which is much worse after eating, sour eructations, salivation, dizziness, hot sensations, gagging at night, trembling over entire body, cessation of menstruation.

A significant phenomenon which should be taken into account in connection with evaluating these complaints is that while they are of the category of complaints, they are really given to the numerous physicians whom the patient has already defeated thus far, in a thoroughly non-complaining manner. On the contrary, the evidence is frequently unmistakable that the patient enjoys the verbalization of these complaints and the dramatization of them. None the less, she shows the evidences of her disorder.

On admission to Stony Lodge she weighed only 80 pounds, was helpless from weakness and emaciation, lying curled up in a bed which had to be equipped with numerous pillows and props as well as warming pads. She

usually lies on her abdomen, writhes, and contorts her body, patting and kneading various presumably painful parts thereof. Her sensorium and intellectual functions are intact. She is ultra-co-operative in any manifestations of interest in her complaints on the part of the medical and nursing staffs, but becomes petulant, resistive, and at times quite bitter and venomous in her complaints when contradicted or "neglected" according to her definition of neglect. She craves and demands continuous attention, and in spite of her precarious gastrointestinal functioning, is made readily happy and contented by having anything to take in her mouth and swallow.

In the course of attempts to cultivate in her a little realistic auto-criticism the suggestion was made that she be placed on one of the popular varieties of pre-digested baby foods. For a time she thrived much better on this, and only yesterday when a little additional pressure was exerted towards objectivity and maturity, she begged to be put back on the "baby food."

She said, "I don't know what's the matter with me. I am extremely dizzy. I am seeing spots for one hour. I am so glad you came up. I have a violent reaction in the right side of my abdomen, which pushes up to my back, because things don't seem to go down. This dizziness is the last straw. I have been trying to sit tight with the pain most of the day. I get contraction in the lower bowel. I get hot in my head, sick in my stomach. I have contraction of the rectum, an enormous amount of gas, a fluttering feeling, and get out of breath. Please don't think me a baby because I'm awfully uncomfortable, doctor. I haven't menstruated since the beginning of the summer—of course, the passing of mucus and little bits of blood from the bowels. But this takes the biscuit. I am so weak I can hardly get out of bed, my flicker. Be an angel and get me comfy. I have been sick two years. I went down from one hundred and ten pounds to eighty-one. I am a yellow old hag, who needs to be de-bugged and de-loused. [Laughs.] Don't tell me I have a sense of humor. You are being grand to me, and it's damned difficult to hang on."

Should an attempt be made in the course of this chummy, and to the patient obviously enjoyable monologue, to bring her tactfully down to earth by attempting some explanation of the psychodynamics involved, she impatiently and yet in a somewhat patronizing manner switches the trend of the conversation back to origins. The doctor's original diagnosis two years ago was "intestinal influenza," and there the matter rests. She calls the physician "my darling," is free and utterly "unself-conscious" about accidentally exposing her breasts and legs in searching for comfortable poses in bed, and showers one with her appreciation of the medical and nursing attention given her. At another time she says, "Doctor, don't you think I ought to change to baby food again; I keep pushing up all the time. Everything ferments and I keep making gas, which isn't very romantic. I keep making "garbie" (garbage) all the time. I know I'm a terrible nuisance all the time but I can't help it. I know that you understand me and that you're going to do everything you can to help, aren't you? This really is a physical thing, and don't you think we can get on a medical basis?" Sterile hypodermics, or for that matter any other medication, immediately relieves her complaints of abdominal cramps, gaseous distention, and pain.

Now while it is obvious that an attempt has been made thus far in this presentation to focus upon those phenomena which are expressive of the total, or personality reactions, I would not have you come to the conclusion that her somatic or part-function pathology has not been thoroughly investigated. While this is the first time that a psychiatric approach has been made to the case, she has been treated in the course of the past two years by a large number of general practitioners and nonpsychiatric specialists in Chicago, New York, and elsewhere.

She was brought to Stony Lodge from a first-class general hospital in New York City, where she had a most searching examination and study of somatic factors. Eight intestinal series were negative, except for a low atonic stomach. X-ray of the chest and gallbladder were negative. Blood count and blood chemistry normal. She has had daily gastric lavage and enemata, has been fed at one time for

five days by means of a duodenal tube, has been on insulin treatment and various specialized diets, and has been diagnosed as suffering from Addison's disease, glandular dyscrasia, gastrointestinal neurosis. On two separate occasions basal metabolism tests showed a minus 12.

A most careful physical, neurological and endocrine examination on admission to Stony Lodge was negative, except for marked emaciation, especially in legs and arms; a slightly deviated nasal septum; atrophic tonsils; palpable anterior and posterior cervical lymph nodes; marked emaciation of abdominal wall and surface discoloration due to a burn from an electric pad; a scar marking the site of operation for a ventral suspension; marked tendency to tenseness of abdominal muscles on slightest touch, but no evidence of pain or tenderness. There is some pigmentation of face and body, but not typically bronze in appearance. X-ray examination shows no calcification of suprarenal glands. Blood pressure, 120/74.

So much for the physical deviations. It is pertinent to a proper understanding of this case to mention at this point that the onset of her gastrointestinal preoccupation did not really take place two years ago, although the details of this event might incline one to an emphasis of this point. It was Christmas Eve, and the patient's brother and his wife, as well as some other relatives, had gathered for a family celebration. Suddenly, and quite out of a clear sky the patient began to cough, developed a fever, abdominal pain and diarrhea, thus unfortunately converting the Christmas party into a rather general preoccupation with her and her illness. The real onset of the difficulty, however, extends back some 13 years, when the patient was 27. She was visiting an aunt in St. Louis, was menstruating at the time, and similarly, quite out of a clear sky, she had her first intestinal attack. This attack occurred in the latter part of August. Some months previously she had also been to St. Louis on a visit and had become engaged to a man who later turned out to be quite worthless and the engagement was broken.

No distinct temporal relationship between this event and the onset of her

trouble can be established on superficial questioning of patient. The attacks recurred two or three times a year after that, always while she was at home, although she did a good deal of pleasure traveling during this time, and always while she was menstruating. Repeatedly they occurred in the month of August.

This went on for several years until we come again to an obscure and somewhat suspicious temporal relationship. Her brother was at the time at Harvard and fell ill with influenza. Her mother and she received the news and subsequently both had an attack, allegedly, of influenza. Matters became increasingly worse with the patient, requiring the joint efforts of internists, gynecologists, and surgeons. Vaccine therapy, appendectomy, and ventral fixation followed in rapid succession, but the patient did not recover until some two years later, when we come upon another obscure temporal relationship, namely, an apoplectic stroke on the part of her father which necessitated hospitalization. The patient got up from her long confinement in bed in order to be able to visit her father. There followed about eight or nine years of relative freedom from gastrointestinal complaints until the December, 1932, already alluded to. Here we again come upon a significant but less obscure temporal relationship. The patient, after having terminated another in a series of engagements, met and fell in love with an Englishman, some five years her senior, an ex-army man who had been more or less holidaying at Hollywood and Palm Beach. He behaved as though he reciprocated the patient's affection, but was apparently also a very practical-minded gentleman, for he did not permit his ardor to blind him to the possibility of acquiring along with the patient a substantial financial subsidy for life. He called it a "dot" but was specific enough to insist upon a guarantee of a fifteen thousand dollar annual income for life. This led to serious trouble between the patient, who was willing enough, and her relatives, particularly her mother, in the midst of which the present attack set in. The patient still desires this man and thinks she could be happy with him.

Now, no attempt has been made thus far to study and treat the patient

psychoanalytically and I am not in a position to undertake a critical or very precise causal definition of her symptoms or her general disorder, although from what has already been stated, the possibility of a psychodynamic envisagement of the entire problem forces itself upon one's attention.

In the background of this woman's life there is a ninety-two year old, very efficient and very successful maternal grandfather, who amassed quite a large fortune; a spinster maternal aunt who keeps house for this gentleman; another maternal aunt of whom the patient is very fond, and to whom she frequently turned for comfort. This aunt is happily married and has two grown children. The patient's father died of apoplexy, leaving no estate behind him. In the patient's eyes he was the most wonderful father, devoted, kind, but admittedly not very worldly or practical. The mother seems to be, from the management of her daughter's problems, a sound, practical sort of person. There is a brother six years younger than the patient, who is married, and a successful architect. The patient was an only child for six years of her life, indulged and pampered, especially by her father and grandfather, but was nevertheless sent to kindergarten at the age of five. However, just about the time of the arrival of her brother (it is not clear whether this occurred just before or just after the birth), she was withdrawn from school and turned over to a governess who tutored her until the age of twelve.

It throws some light upon the perspicacity of her parents to note the manner in which the arrival of her brother was announced to the patient. She remembers this very well to this day. She had been sent away to spend the day with her aunt and claims not to have had any inkling of the impending event. Later in the day the father came and announced to her that a little baby brother had arrived and brought her some gifts, which she found together with her little brother on arriving home. At any rate, she also gained a governess in connection with this event, did not return to school until six years later, when her brother was about six and took over her governess.

There is no particular advantage in

tracing in detail the patient's subsequent development other than has already been given in connection with the history of her illness. Although she had a very favorable beginning economically, culturally, and in personal equipment, and has had the advantages of a good formal education, much travel, and social opportunity, she is today, at forty, a rather pitiful spinster, not very good to look at and certainly not very easy to live with. She has defeated a great array of physicians in their struggle with her illnesses, has been engaged to be married on quite a number of occasions, always wittingly or otherwise finding herself frustrated in her love life. She is completely dependent economically upon her mother and still finds her greatest satisfaction in an exploitation of her invalidism. If I were to trace in detail her emotional development and use, I would have to do so on the basis of non-psychoanalytical data, and consequently with such important gaps as to make the total picture useless for a strict scientific evaluation.

But I believe I have furnished enough data for a more than fairly justifiable assumption that her complaints and disorders have not been definable in terms of organic or physical categories, certainly not in terms of an irreversible organic pathology, and that there is a unity pervading her difficulties and disorders which has a closer and more intimate relationship to her total personality, to the economics of personal and social adjustment, both on the causal and effectual sides, than to a specific pathology of any one or another of her bodily organs or part-functions.

In view of this patient's past history, her improvement after five months' residence in the hospital might be considered very gratifying indeed. She has gained a great deal of weight and physical strength, is regularly employed in the occupational therapy department, goes for long walks, and frequently attends the cinema in the village. She is much more objective and outgoing and less preoccupied with her subjective complaints.

Now while this patient has not had the benefit of a strict psychoanalytic therapy, it is very doubtful whether the improvement attained would have been possible had it not been for the complete shifting

of emphasis from the somatic to the psychological aspects of the situation which took place with her admission to Stony Lodge.

II

The absence, in connection with the foregoing clinical report, of the kind of data which only a psychoanalytic study of the case could have furnished, need not deter us from employing it as a clinical basis for the purpose of this paper. We have in mind a restatement of the psychiatric point of view, not only as a possibly helpful contribution to a clarification of the troublesome and somewhat futile controversies between the so-called functionalists and organicists, but especially in the hope that a restatement of this issue will add further to the helpful co-operation between psychiatry and other branches of medicine. This is not the first time that it has been my privilege to deal with this question, but I am digressing somewhat in this presentation of it from the usual manner of dealing with it, in that I am taking the liberty of indulging in a bit of biographical introspection. I am entertaining the hope, in so doing, of demonstrating to the non-psychiatric practitioner, at any rate, the evolution of my own interest in the psychiatric point of view, and how I was led to the present conception of it.*

It seems scarcely possible that more than twenty years have elapsed since as an eager and enthusiastic novice in the field of psychiatry I journeyed to Kraepelin's clinic in Munich in response to an insistent urge to challenge a certain dictum which was at that time propounded by the Kraepelinian School of Psychiatry. This dictum was to the effect that an individual's capacity to develop a psychogenic disorder was *prima facie* evidence of an underlying constitutional defect. It seemed to me then preposterous, and in my utter naiveté, quite unfair, to stamp an individual constitutionally defective because he developed a psychological disorder in the wake of and in response to

certain social-psychological experiences which at last had become unendurable to him.

I was at that time very much taken up with the rich clinical material of the Criminal Department of St. Elizabeth's Hospital in Washington. Important practical as well as clinical considerations made necessary a careful scrutiny and evaluation of psychopathological manifestations which could not be completely identified with the accepted nosological entities of that day. Not having been too excessively steeped in the prevalent psychiatric preconceptions, I took these manifestations at their face value and endeavored to understand them as reactions of the total personality to certain exceptionally trying conditions of life. These manifestations were in the nature of more or less acute and transient panic states of terror and confusion; flight reactions in the nature of more or less profound catatonic-like and depressive states, and efforts at defense and retaliation in the form of hallucinatory, delusional, and psychomotor phenomena in individuals who in some instances seemed to be burdened with constitutional handicaps for meeting exceptional stresses of life, but in many other instances manifested no discoverable indications of this nature.

The experiences of arrest and imprisonment obviously had the effect upon these individuals of psychological traumatism and serious frustration, the true psychopathological significance of which only became clear to me on my later acquaintance with the contributions of Freud. But this experience served to focus my attention on the causal significance of sociopsychological factors in human maladjustment and disease.

St. Elizabeth's Hospital, under the leadership of Dr. William A. White, was even in those days quite amply equipped for a dependable investigation of the chemical, toxic, and somatic factors in mental disease. It was well steeped in the materialistic and mechanistic traditions of the day which came in the wake of the brilliant contributions from the fields of physiology, biochemistry, and neuropathology. To a novice like myself, only slightly acquainted with the noble tradition in mental medicine which antedated

* The gist of what follows was presented at a symposium at a joint meeting of the New York Neurological Society, and the Neurological Section of the New York Academy of Medicine, November 1, 1932. It has not been published in its entirety before.

the nineteenth century and Darwin, a period when psychological phenomena were still accorded an adequate hearing, and being not at all acquainted with the psychological renaissance that had its birth and was reaching its adolescence in Vienna, the Kraepelinian dictum to which I have already referred undoubtedly assumed an undeserved importance.

At any rate, heedless of the possible consequences, I plunged into debt for the first time in my life and took myself off to Munich. I am sure that many of my contemporaries have shared with me the unforgettable experience of sitting at the feet of the late Professor Kraepelin and of coming in contact with the atmosphere of that clinic. As I realize my reactions in retrospect they were of two distinct categories. On the one hand, I was amazed and fascinated by the many things which were capable of demonstration in a mental patient that had utterly escaped my notice up to then. But I also had a different kind of reaction. It seemed to me that a very outstanding aim of the Munich enterprise was the justification of Kraepelin's nosological categories.

While I was not unacquainted with the wise caution of Adolf Meyer and other American psychiatrists against an uncritical acceptance of the Kraepelinian nosological schematization, it was not difficult to subordinate this question to what seemed to me the more pressing one of psychogenesis in psychopathology. Strangely enough, it was an organicist, one of the wisest of them all, the late Professor Alzheimer, who gave me the most encouragement for the pursuit of my later work. I shall always consider it an outstanding bit of good fortune that after leaving Kraepelin I spent a little while with Professor Ziehen in Berlin.

If I needed any further encouragement towards a complete emancipation from rigid nosological preoccupations, I certainly gained it from my contact with Professor Ziehen. Day in and day out I watched the meticulous search for and attention to all the clinical facts in a patient, no matter what their ultimate value might come to be in the total scheme of things. There was no deliberate or unwitting slighting of any fact, no attempt to bring it in line with any preconceived nosological formulae—a most

encouraging and valuable reaction to the impression of a closed system, at any rate as far as the dementia-praecox-manic-depressive problem was concerned, that one inevitably carried away from Munich. It was here too that I saw for the first time some classical and quite dramatic cases of major hysteria, a circumstance which made the necessity of going westward and home, instead of journeying east to Vienna, a most regrettable and poignant disappointment. Those who have known Professor Ziehen know what an earnest and meticulous scientist he was and how completely interests of a biochemical, bacteriological, and neuropathological nature were represented at the Charité in his day. But psychological phenomena—qua psychological phenomena—were accorded the same respectful attention as other kinds of clinical manifestations.

No psychiatrist who has had the good fortune of contacting with the personalities that it was my good fortune to meet that memorable Fall of 1911 can fail to appreciate the debt one owes to such an experience. But I was at that time, so to speak, "hipped" on a certain subject. I wanted to know the "why" of certain psychopathological phenomena; I wanted to know, moreover, whether the common strains and stresses of life incident to human experience and human relations had any place in the causal scheme of psychopathology. My prison psychotic cases were free from toxic, traumatic, or other physical disorders that might have accounted for the difficulty, and while some of them might have been placed by a stretch of the imagination within the categories of dementia-praecox or manic-depressive, it left me no nearer any sort of satisfactory understanding of what was actually happening. Moreover, these acutely and severely ill people, when placed under the humane, intelligent, and unprejudiced régime of a mental hospital, frequently improved or even recovered very rapidly. I did not know then that what I was searching for was a "dynamics" of psychopathology. No enlightenment with reference to this came to me from my European experience.

The enthusiasm and excellence of Plaut's laboratory certainly convinced one of the causal significance of syphilis,

but in a paper published somewhat later I revealed my dissatisfaction, and naïveté perhaps as well, when I failed to find in a most meticulous serological and neuropathological study of the paretic the explanation why one paretic was gay and euphoric and another in the next bed to him spread a thick gloom all about him by his depressive and hypochondriacal complaints. Rudin's figures and enthusiasm for genetics helped a lot where hereditary elements were in evidence. But even here no explanation was forthcoming as regards the why and meaning of symptoms.

Krapelin's and Ziehen's remarkable skill in detecting and demonstrating symptoms certainly helped to enrich one's phenomenological horizon, but that was practically all, even if one did find comfort in being able to label a patient with a name. What did the patient have to do with all of this? Was he merely a passive and unresponsive object of all these various causes that were alleged to be responsible for his disorder? What was the relation of ordinary, every-day manifestations of grief and joy, of shyness and embarrassment, of anger and love and hate, which we observed in ourselves and our acquaintances and friends to these dramatic manifestations of our patients? These were legitimate questions for a novice in psychiatry.

When one's friend sought comfort and encouragement in his distress, or sympathy in his sorrow, we did what we could with the plain and commonplace facts of human relations at our disposal. One accorded to the common frustrations and disappointments and privations incident to the bread-life and the love-life of man their due significance as causes of unhappiness, maladjustment, and malaise and proceeded to relieve the distress incident to them by such measures as common sense and one's concern or friendship or love for another human being prompted. But as soon as these distresses acquired a degree of profundity which brought them within the category of one or another of the "ologies" one was told by a materialistically obsessed nineteenth century science that all these precious and humble facts in the relation of man to man were inadequate and even meaningless in any scheme of scientific psychiatry.

Above all, one was to shun all possible allurements of a "teleology" in human relations as the Devil shuns holy water, for man was nothing but a machine, a biological-mechanical contrivance for the transformation of energy which expressed itself in human life and human conduct. To a novice like myself this mechanistic conception did not seem to suffice. For one thing, while it may have accounted for the physiological processes back of human action and conduct, it certainly fell short of furnishing any clue whatsoever to motive and purpose, the touchstones of human relations.

My prison-psychotic patients came to me frequently from veritable dens of iniquity, having lived for months or years under an atmosphere of ignorance, starvation, hate, and cruelty, in some of the military and naval prisons of that day, and at a time when men who had been deprived of normal sexual outlet for months and even years on a stretch were still being sentenced to ten years of hard labor under confinement if detected in a homosexual act. It did not require toxic or chemical or organic explanations of any other kind to account for their psychopathological reactions to that type of experience, and while phenomenologically one could observe similar psychological reactions in patients suffering from undoubted organic disease of the central nervous system, it did not seem inconsistent to attribute the prison-psychotic manifestations to psychological and social causes.

III

I fear I've already burdened your patience beyond endurance by this recital of personal reminiscences, but whether you believe it or not, I am not motivated by any desire to talk about myself. I am using my own mental attitude as illustrative of what must have been the mental attitude of other young psychiatrists of that period if the clinical material with which they had to deal offered any challenge to their minds, and indeed they had already become acquainted with the stimulating and confusing contributions of Sigmond's theory. The difficulty of understanding and managing their psychiatric terms of purely structural

cal issues would not have been minimized even if they had been fully acquainted with the brilliant contributions in neuro-anatomy and neuropathology of such men as Brodmann, Nissl, Alzheimer, Cajal, and Von Monakow. The facts of brain localization, while they had not reached the rich status of today, did not succeed in eliminating the suspicion that any inclusive notions of brain-mind parallelism only told part of the story. Such a well informed neuropathologist as our own Adolf Meyer stated the issue squarely as far back as his Kankakee days: After having demonstrated at an autopsy to a coroner's jury the cause of the accidental death of a psychotic patient, he was asked by them to show them the brain changes which were responsible for the man's insanity, to which he replied that the explanation of that was to be sought in the record of the patient's life and not in changes in the brain.

No matter how thoroughly acquainted our imaginary psychiatrist of twenty-odd years ago might have been with the physiological researches of that day, he could not have escaped the suspicion that a higher type of integration than physiology had been able to demonstrate must lie at the basis of human conduct. He might have anticipated what Cannon said in 1927, when he spoke of "affect" as "a function" of the animal's behavior. In terms of human conduct, man as a social being transcends the various physiological processes which enter into the functioning of a biological organism, the "whole" being greater and different than the sum of its parts. The same might be said with reference to such enlightenment as might be derived from the emerging research of twenty years ago in the field of biochemistry.

If he was at all challenged by his clinical material he still would have been troubled by the following queries:

(1) Since structural, physiological, and chemical factors do not suffice to account completely for the cause of mental disease, what about psychological and social factors? Are psychological factors to be accorded the same validity and significance in the causal chain as non-psychological factors in the investigation of mental disease?

(2) Is the concept of so-called "func-

tional disease" a valid concept, or must disturbance of function always depend upon structural modification?

(3) Is one compelled to depend upon pluralistic or parallelistic conceptions of mind or is there a possibility of a unitary concept according to which psychological phenomena are subject to laws of their own equally applicable to normal and abnormal functioning?

(4) What about the questions of meaning and purpose in the fields of psychology and psychopathology? Specifically, is the functioning of the personality as a whole—that is activity or passivity—which underlies man's conduct as a social being, free or deterministic or fortuitous? Is mental disease the fortuitous or haphazard reflection of an underlying disorder of function or structure or does it possess meaning in terms of human motive and human purpose?

(5) Is one to accord the various forms of psychotherapy which have been more or less successfully employed from time immemorial any scientific validity, and is there anything to the significant findings of the hypnotic state? Or, must therapy of mental disease be limited to indirect methods by way of physical, chemical or biological channels?

He need not have been deterred from posing these questions by the materialistically prejudiced scientific clamor of that day. If he had an inquiring mind at all, he must have discovered the joker in this scientific game, namely, that the refusal to accord psychological data scientific validity was not science at all but the crassest kind of prejudice, an inheritance of nineteenth century materialism.

I am speaking of conditions existing two decades and more ago, but the same is true today to a very large extent, unless one accords an honest and unprejudiced hearing to the contributions of psycho-analytic psychology of the past thirty-five years and more. These contributions have furnished an adequate answer to the queries we have stated above, and to a great many others besides, which are at last promising a truly scientific approach to mental disease.

IV

It is quite unnecessary to reiterate here with any degree of detail the con-

contributions of psychoanalytic psychology to the understanding and management of the problems of psychiatry, and neurology and disease generally as well as to the elucidation of so called normal functioning.

No better statement of these relationships has been written since the memorable publication in 1915 of Jelliffe's and White's textbook on nervous diseases. Notwithstanding the fact that many valuable contributions which specifically affect the problem of mental disease have been made since then by Freud and others of the psychoanalytic school this textbook was the first successful attempt, as far as I know, at a complete elaboration of a unitary concept of disease of the personality as a whole. In addition to a dependable statement of the "what" of these disorders it attacks courageously the problems of the "how" and the "why," of the entire question of personality disorder and maladjustment.

Mental disease is a disorder of the personality as a whole. The personality as a whole embraces all those structures and integrations of function which are familiar to us from the fields of anatomy, physiology, and biochemistry, and also those higher integrations which are conditioned by the racial heritage of man and which begin to emerge with the birth of the individual and his first contacts with other human beings.

These higher integrations at the psychic level are intended not only to serve the immediate adjustive requirements of man in his impacts with reality, but are engaged from the moment of birth until the death of the individual in the important task of maintaining a satisfactory adjustment between two sets of forces which contend for the mastery of the individual and his conduct, namely, the forces of nature or instinct and those of nurture or culture. Disease and maladjustment of the personality as a whole, no matter under what guise they may emerge inevitably and unescapably have some relation to this internal, subjective aspect of the personality.

Thus the causes of the disorders of the personality as a whole (of mental disease) cannot be defined by reference solely to the immediate precipitating event whether this event be a brain

tumor, or a vascular brain insult on the one hand, or a frustrated love affair or some other form of frustration or privation on the other hand. The real explanation of mental disorder lies in the universal and what to all intents and purposes has come to be the natural intrapsychic conflict of civilized man.

The immediate precipitating event, whether it is of an organic or toxic or psychological nature, inhibits or destroys the capacity of the self to deal adequately with this intrapsychic conflict, and the symptoms which a given disorder reflects are indicative of the specific way in which the conflict is being dealt with. Now all of this, of course, must remain unintelligible if one limits his vision to a psychology of consciousness and refuses to accord equal consideration to the vastly more important psychology of the "unconscious."

Neither can an adequate conception of psychopathology be had if one follows the *tabula rasa* theory of human nature and indulges his narcissism to the extent of insisting that since the new individual comes into the world with a clear slate upon which his destiny might be written at will, he can mold this new individual entirely according to his desire. This is the doctrine advanced by those modern psychophobists who call themselves "behaviorists."

Jelliffe has stated the social heritage implications of psychopathology with almost poetic beauty when he said in that memorable textbook:

Even in possibly the earlier days of Indo Germanic beginnings is found this dual aspect of the individual and the race and even more interestingly the warning lest the polarity be lost and the inertia of death attained by an equalization of the opposing forces. Beware of being caught in the pathway of opposites, purports to be a quotation of Hindu antiquity which in modern mechanics means 'being caught on dead center'."

He says further:

The formulations followed in this volume assume that whatever is called 'Nature' has provided for this contingency and has accumulated such phyletic memories (Semon's engrammes) as to push forward with greater dynamic potential one of these pairs of opposites namely the phylum maintenance. Hence race propagation is

the loaded side of life's revolving wheel, and self-preservation its obedient opposite. It is not a mere coincidence that theology should have phrased the same thought in the statement that "he that findeth his life shall lose it: and he that loseth his life for my sake shall find it."

Intrapsychic conflict, the tensions and anxiety incident to the opposing forces within the constitution of man, is thus seen to be the natural destiny of man. So-called normality reflects the achievement of a satisfactory adjustment between these contending forces. That this so-called normality ordinarily goes hand in hand with somatic integrity does not signify at all that structural and physical health is an absolute guarantee against those failures of adjustment which are reflected in the field of psychopathology. It is not an uncommon experience in the practice of neurology that a diagnosis of "functional disorder," so-called by exclusion, after a most meticulous search for somatic factors leaves one disappointed.

I think we are justified in following Freud, when he says that "The meaning of a symptom lies in its connection with the life of the patient." The wish-fulfillment character of sensory falsifications such as illusions and hallucinations is not invalidated by the circumstance that these manifestations might be released by a toxemia or an encephalopathy.

The compensatory or defensive character of a delusion is not disproved by the circumstance that it occurs in a paretic. While the compulsion neurotic differs from the hysteria in the psychological dynamics and content which underlie these disorders, they both illustrate types of situations in which the claims of instinct have experienced an unnecessarily excessive restriction or denial in response to excessive taboos imposed upon the individual by that side of his nature which reflects the claims of culture and education. The explanation of the psychoneurosis does not lie in the psychoneurotic's friction with his environment but in the intrapsychic conflict. In so far as the claims of society or culture—claims which the individual is obliged to heed almost from the moment of birth—constitute one element of this conflict, they have become internalized and to all intents and purposes part of the nature

of the individual, and have acquired a degree of significance and power approaching the significance and power of instinct itself.

In the case of the psychotic the situation might be said to be the reverse of what happens in the psychoneurotic without invalidating the conception that basically the same forces are at work as in the psychoneuroses. Through the abandonment of the sense of reality and of auto-criticism the claims of culture are increasingly ignored. The difficulty here, obviously, is primarily with all those forces of control and adaptation which are embodied in the psychomotor equipment of the conscious self. Any traumatization of this equipment, whether of somatic or toxic or psychological nature, may initiate the regressive trend which makes possible the uncritical release, as occurs, potentially, in the normal dream state, of the instinctual drives which had been mastered in the service of reality before the onset of the psychosis.

It must be clear by now that the point of view which I am defending is the psychoanalytic approach to psychiatry. There is no justification for the criticism that this approach is in any way antagonistic to scientific method. Psychoanalysis is to traditional psychiatry what histology is to anatomy: it is an extension and refinement of the psychiatric instrument. It had its origin in an endeavor to find a more reliable instrument for the definition and the treatment of psychopathological disorders. Its entire phenomenological and conceptual structure has been built up out of clinical experience with psychopathological manifestations, and where conceptual constructions outdistanced empiricism Freud never hesitated to point to this. The psychological mechanisms which came to light in connection with the study of the dream have been proved to be valid by earnest investigators in practically every civilized part of the world. The concepts of the "unconscious" and of infantile sexuality as well as the so-called libido theory are no longer controversial topics.

The application of the psychoanalytic instrument to psychiatry naturally goes beyond mere description and prognostication on the basis of spontaneous outcomes of certain symptom complexes. While it

has stimulated a much more minute and careful observation of the manifestations of psychical disorder, it aims furthermore to discern the meaning of these revelations, the "whys" and the "wherefores" of the patients' symptoms. It goes beyond this, and viewing disease as an endeavor, albeit an unsuccessful endeavor, at adaptation, it postulates the question in each case: "What is the patient trying to achieve by means of his disorder?" Or, in other words, what need is the neurosis or psychosis fulfilling? This is a very important step in advance of an approach which saw in these disorders merely evidences of failure. That every neurosis or psychosis represents a failure of adaptation cannot be gainsaid, but it is also true that every disorder of this nature is capable of revealing to us the specific issues which created the problem and which the patient is endeavoring to solve by means of his disorder.

The significance for the destiny of the individual of such factors as hereditary predisposition, native endowment, developmental vicissitudes, and accidents of life, is in the final analysis most accurately evaluated when viewed in the light of their effect upon this internal, dynamic play of forces. It is my thesis that the effect of somatic pathology upon the destiny of the individual can likewise be illuminated to the profit of patient and physician or surgeon when due consideration is given to this play of antagonistic forces within the personality.

It does not in the least invalidate the scientific approach to a somatic disease to include in the scrutiny and management of it, the fact, that whatever else it may be, it is also in the nature of a stimulus to the total personality, an experience to which the individual is obliged to react, and the nature and character of this reaction frequently depends more upon the type of personality one is dealing with, than upon the nature of the somatic disorder. Indeed, at times it is the maladjustment of the personality itself which makes possible and necessary the somatic disorder. Our chief concern then becomes, as in the case which I have cited, not so much to rid the patient of an existing symptom, but to free him of the need for symptom formation. This is, of course, particu-

larly the case in the so-called strictly psychogenetic disorders, when a correct therapeutic procedure always calls for a subordination of the claims of the symptoms to the requirements of the personality as a whole.

The defensive nature of the disorder of the patient referred to earlier, even in the absence of a thorough-going psychoanalytic investigation of her case, must be obvious. The resort to such a crippling of personality as she has eventually achieved must be a manifestation of conflict or maladjustment of the total personality. Naturally, I am not assuming from the manner in which I speak of this situation, something in the nature of conscious and deliberate intention. Neither is her problem understandable in terms of contemporary issues only, but requires an adequate appreciation of the historical background and evolution of her personality.

The outcome in a given disease depends not only upon the efforts the physician puts forth in combating the disease, but also and frequently enough, particularly so, upon what the patient himself does to his disease. He may see it as a stimulus to the release of all his potentialities for recuperation and life and the battle is won without much interference on the physician's part. But he may also see in it an opportunity for a release of a death impulse which no physician's skill in dealing with the somatic disorder is able to check. The somatic disease may, as we have seen, express a problem which cannot be defined in terms of the chemical or anatomical laboratory, but its implications extend into the laboratory of life as it is actually lived in the home, the school, the playground, the workshop, and so on.

This view of the matter does not necessitate an ignoring of the manifold somatic issues of a traumatic or toxic or constitutional nature which may enter into the determination of human conduct and human relations, but it is imperative to scrutinize these somatic factors not only for their effect upon the individual as a biologic organism, but as a human personality and social being.

The inescapable limitations of space do not permit of a thoroughgoing consideration of the full implications of the topics

I have so briefly touched upon, but since I am endeavoring to focus your attention upon the rôle of personality in disease I am obliged to attempt at least a bare outline of the psychopathologist's view of this question of human personality. I shall assume that we need not concern ourselves here with the structural and physiological aspects of the matter. But I think it might be helpful to indicate at the outset how frequently we are obliged to condemn something in the conduct of man as a social being which we recognize as natural and healthy from a biological standpoint. Unless, indeed, we belong to those rare natures who have succeeded in acquiring a kind of concept of biology which embraces the social implications of life and conduct.

At any rate, the antagonisms between the biological and social requirements of man are universal and permanent. The unconditioned dispositions which man brings with him at birth have to undergo a degree of repression and taming and transformation in order to meet the requirements of social adjustment which is difficult and painful at its best. Exposure of the infant and child to a too severe process of socialization of his biological nature renders difficult or impossible the indispensable degree of satisfactory living out of the life of instinct and leads to those pathological manifestations of personality and conduct which we know as the various distortions, ineffectual compromises, and substitutive modes of gratification which constitute the neurosis.

Somatic disease is frequently employed as a substitutive mode of gratification of a thwarted instinct. No greater love is

man capable of than the love some patients bestow upon a so-called colitis or cardiac palpitation. Conversely, the failure to subject biological nature to the necessary degree of taming and control is reflected in the manifestations of perversion, insanity, and criminal conduct.

Psychoanalytic psychology, which more than any other approach to the understanding of the human personality has illuminated these matters for us, carries the promise through its special technic of reconditioning the individual to a more adequate capacity for dealing with this internal and inevitable conflict. Death alone frees the individual from the burden of adjustment. Unfortunately, the somatic disguises which patients employ in dealing with their conflicts are apt to elude us if we are too steeped in a materialistic conception of the personality.

Conspiracies between the physician and the patient's unconscious motivations tend to foster and put a premium upon deception. The substitutive forms of gratification become fixated; medicine taking, dietary rituals, surgical castrative indulgences, and the doctor's devotion to the case combine to create a situation which renders the process of reconditioning unnecessarily difficult and sometimes impossible. The secondary and often very substantial gain from illness in denying a troublesome aspect of one's own nature or in gaining mastery over one's environment determines the patient to hang on to his illness with all the might of his unconscious, instinctive strivings, and the defeat of our efforts is a foregone conclusion.

STONY LODGE

CANCER COMMITTEE TO HOLD EXHIBIT

An exhibit of the facilities available in New York for the diagnosis and treatment of cancer and for the care of the needy cancer patient is being planned by the New York City Cancer Committee, in conjunction with a number of hospitals in the City, to be held at the Hotel Plaza, May 14 to 20. Admission is free and all are cordially invited to attend.

The hospitals which have so far accepted the invitation to participate in the Cancer Committee exhibit are:

Bellevue Hospital and Division of Cancer of the Department of Hospitals, Kane Pavilion of the Home for Incurables, Lenox Hill Hospital, Mount Sinai Hospital, Memorial Hospital, Montefiore Hospital, New York City Cancer Institute, New York Hospital, New York Infirmary for Women and Children, New York Skin and Cancer Unit of the New York Postgraduate Hospital, Presbyterian Hospital, St. Luke's Hospital, St. Rose's Free Home for Incurable Cancer, Visiting Nurse Service (Henry Street), Woman's Hospital, Welfare Council of New York City.

BRONCHOGRAPHY AND BRONCHIECTASIS

I. SCOTTY SCHAPIRO, M.D., AND LEOPOLD JACHES, M.D.

From the Chest Service of the Mount Sinai Hospital

NEW YORK CITY

There is probably no aspect of diseases of the lung upon which bronchography has not thrown considerable light in recent years. In tuberculosis, lung abscess, bronchiectasis, benign and malignant tumors, and in obscure diseases of the lungs, the application of the bronchographic method has greatly clarified our conception of the disease process present, often proving our principal means of establishing an accurate diagnosis. This method has been of outstanding value in two distinct ways: first, in the diagnosis of the pathological lesion present in the lungs; second, in its precise localization to a bronchus and its corresponding pulmonary segment.

Amiel Glass has detailed with admirable exactness the anatomy of the bronchi and lung segments, thus demonstrating the definite and constant relationship of a bronchus to its particular lung segment.¹ With this knowledge, therefore, it is now possible to predict with confidence whether a lesion will be found in the posterior, anterior, or axillary portion of the lung field. In operations upon the chest, such as drainage of a lung abscess, pneumonectomy or intrapleural compression, this knowledge is vitally important. In lung abscess, for instance, it may determine whether the outcome will be entrance into the free pleural cavity, with disastrous results, or immediate drainage, with subsequent cure.

The scope of this paper does not allow enlargement upon this aspect of the work. Its purpose is to demonstrate the value of bronchography in the diagnosis of diseases of the chest, particularly with reference to bronchiectasis. This procedure has provided a remarkably accurate method for ascertaining the anatomical condition of the bronchial wall. In cases where early disease of the bronchi is suspected confirmation must await bronchographic findings. Sometimes, when no pathological process has

even been suspected, bronchography has revealed the presence of bronchiectasis. Finally, various forms of bronchiectasis, now recognized as one of the commonest diseases of the lungs, have only recently attained clinical classification. Indeed, the dry and hemoptotic forms have been established as entities only since the introduction of this method. As a complication of other diseases of the chest, particularly lung abscess, tuberculosis, and obstructive lesions, bronchiectasis has been shown to be a most important factor. In lung abscess, after the original lesion has been drained, continued cough and expectoration may be due to an adjacent involvement of the bronchial wall. The cause of hemoptysis in an apparently healed tuberculosis of the upper lobe may be discovered in an unsuspected bronchiectasis of the lower lobe. The persistence of symptoms following the removal of a benign tumor or foreign body of a bronchus has been explained by the presence of infection and bronchiectasis behind the obstruction. Bronchography is the only available method for the definite demonstration of the extent and character of these complicating bronchiectatic lesions.

The cases have been chosen to present both clinically and bronchographically the development of diseases of the bronchi from their earliest manifestations to their most advanced stages. They are divided into four groups. The first, showing cylindrical dilatations and varicosities, is composed clinically of cases of chronic bronchitis usually associated with a chronic sinusitis. The second includes a group exhibiting more extensive damage to the walls developing in the course of a severe bronchopneumonia. The third group comprises cases presenting the classical textbook picture of advanced bronchiectasis with extensive involvement of the bronchi. The fourth, a large and important group only recently

Fig. 2

Fig. 1

classified, shows the development of bronchiectasis as a complication of a specific condition in the chest, such as lung abscess or tuberculosis.

The earliest changes in the walls of the bronchi are seen in cases of chronic bronchitis usually associated with a chronic sinusitis. The history in these cases may be that after one of the childhood diseases such as measles or pertussis the patient was left with a chronic cough causing little or no expectoration. In later years many of these patients develop a sinusitis with a postnasal discharge which aggravates the cough and expectoration. Clinically these patients are not seriously ill. The cough is the most annoying symptom, expectoration being slight. Physical examination may reveal only a few râles at the bases, or may be entirely negative. In such cases bronchography reveals only some mild changes in the contour of the bronchial wall. This is manifested by a pouching of the bronchial wall confined mainly to the larger bronchi, or more distinct changes such as varicosities and cylindrical dilatation of the bronchi. This cylindrical dilatation is shown by the fact that the bronchi do not diminish in caliber as they extend toward the periphery. Occasionally the changes may be more marked. (See Figure 1.)

This is the bronchogram of a patient 25 years of age who, since pertussis in infancy and pneumonia at 3 and 8 years of age, has had a cough with slight expectoration. A few years ago, following the development of a chronic sinusitis, both the cough and expectoration increased, the latter, however, never exceeding $\frac{1}{2}$ oz. daily. The bronchogram shows marked cylindrical dilatations and varicosities of the bronchi with some changes in the terminal portion. The rôle of sinusitis has been emphasized in these cases of chronic bronchitis, not because of its etiological importance, but because of its influence in bringing about or adversely affecting episodes of subacute or chronic pneumonitis and so increasing the damage to the bronchial wall. Therapy in these cases is directed to the cure of the lesion in the upper respiratory tract.

The next group presents evidences of destruction of the bronchial wall follow-

ing immediately upon initial infection. These changes occur as a result of a severe type of inflammatory disease of the lungs—a so-called suppurative bronchiopneumonia. In these cases of severe bronchiopneumonia, however, the bronchiectatic cavities may be few and small, or numerous and severe enough to cause death. An example of the very early formation of a bronchiectatic cavity is seen in the following case. (See Figure 2.) The patient is a boy of 18 who, 20 days before admission to the hospital, developed high fever and a dry hacking cough. The fever subsided somewhat at the end of the week, but the patient then began to cough up thick, green, purulent, non-foul sputum. For the next few weeks he ran a septic temperature with cough and profuse sputum. The purulent nature of the expectoration was its most striking characteristic. X-ray showed a pneumonic process with a faint suggestion of a fluid level within the infiltrated area. Bronchogram revealed an early terminal dilatation of one of the right lower lobe bronchi.

What the ultimate result will be in this type of case cannot be predicted, for nobody has as yet followed these early cases sufficiently long to be able to foretell with confidence. Bronchography has begun to reveal to us the earlier phase of this disease. However, we do see many cases whose past history is similar to the one above and who enter the hospital a few years after initial acute illness only because of increased cough and profuse expectoration. Bronchography will show marked bronchiectasis in many of these cases. The case presented above may represent the early phase of this disease.

How rapidly an advanced stage may develop in these cases is shown by the patient who, after appendectomy, developed a postoperative atelectasis which, in turn, was followed by a severe bronchiopneumonia. A month later bronchoscopy revealed thick pus in the right lower lobe without definite bronchiectasis. Two months later a bronchogram showed extensive bronchiectasis in right lower lobe. (See Figure 3.)

In some instances the patient may succumb to the infection in the acute stage. Figure 4 is the bronchogram of a man of 40 who had had asthmatic attacks for 20

Fig. 3

Fig. 4

years. Following a severe asthmatic attack patient was given sedatives which left him unconscious for 36 hours. He developed, thereafter, fever, septic in course, and profuse purulent sputum. Bronchography showed the presence of large bronchiectatic cavities. The patient died from the severity of the infection. (See Figure 4.)

Many of these patients, studied for a few years, have shown changes in the extent of their lesions; but there has been little relationship between their clinical symptoms and the extent of their pathological lesions. Some, showing decrease in lesions, have exhibited no corresponding diminution of symptoms, and vice versa. It is in this group, showing the early development of bronchiectatic lesion, where injury to the bronchial wall has not yet progressed to the stage at which restitution is impossible, that therapy might be of some avail. Pneumothorax in these early cases has some-

times proven of definite value. Although it has not diminished the size of the bronchial dilatations, it has had a favorable influence upon the cough and expectoration.

The next group, possibly the final result of many of the cases described above, presents the typical textbook picture of bronchiectasis. These cases show the classical signs and symptoms of the disease with marked clubbing of fingers and toes, paroxysmal cough, and expectoration of large amounts of sputum—the usual cases recognized in the period before the introduction of bronchography. Figure 5 shows a severe form involving all the lobes of both the right and left lung. The patient was 22 years old. At the age of 5 he recovered from a severe attack of influenza. Several members of his family died from the disease at that time. Since then he has had occasional attacks of bronchopneumonia with increasing amounts of

Fig. 6

Fig. 5

Fig. 7

Fig. 8

sputum. The bronchogram shows large bronchiectatic cavities throughout the entire lung. These cases form a pathetic and utterly hopeless group, even from a merely palliative point of view. They succumb as a result of severe and progressive bronchopulmonary disease, pulmonary hemorrhage, metastatic brain abscess, or cardiac complications.

The fourth group, consisting of a miscellaneous collection of cases that show development of bronchial changes following specific conditions in the lung, is perhaps the most important. These cases are separated, not because their pathogenesis differs from those we have just discussed, but because their importance has only recently been recognized. As has recently been emphasized by Neuhoof, Potter, and Murphy,² bronchiectasis is an almost constant phenomenon in chronic tuberculosis. Not only is it found in the bronchi in the vicinity of the lesion, but it may be

discovered accidentally in other portions of the lung and found to be the cause of continued cough and expectoration. In adequate thoracoplastic operations bronchiectasis in the lower lobes has accounted in some cases for continuing cough and expectoration.

Destruction of the bronchi is not only an invariable sequel of a chronic lung abscess but often, as well, the predominant feature of the disease in the chronic stage. The so-called "lattice lung," with its extensive fibrosis and bronchial cavitation, is not infrequently met with in long-standing cases. An excellent example of the value of bronchography, not only in revealing the true nature of a lesion, but also in localizing its exact position for operative intervention, is shown in Figures 6 and 7. Four days after submersion this patient developed fever, cough, foul expectoration, and right lower anterior chest pain. X-ray showed an abscess in the lower portion of the right

lung. He was operated upon posteriorly. Since then he continued to cough, expectorating about 8 oz. of green nonodorous material. Two years later he was admitted on account of his persistent cough and expectoration. Bronchoscopy showed bronchiectasis of the right middle lobe and the right lower lobe, especially in the anterolateral branch. The question of the correct operative approach now arose. Bronchography showed the essential lesion to be in the right middle lobe. In this case bronchography localized the lesion, revealing its nature and extent and, in addition, the striking fact that the posterior approach of the first operation, two years before, could not possibly have drained the original abscess.

Obstructive lesions of the bronchi, whether due to a foreign body or to a bronchial lesion, benign or malignant, will, if present for any length of time, cause an infection behind the obstruction, with the subsequent development of bronchiectasis. Often removal of the obstruction does not cure, owing to this complication. Figure 8 shows the severe bronchiectasis which developed behind an obstructing fish-bone in the bronchus.

Since the clinical syndrome of dry bronchiectasis can only be confirmed by means of bronchographic studies, its

recognition is of comparatively recent origin.

In the hemoptotic form, recurring hemoptysis is the outstanding symptom. Many of these patients have very few symptoms referable to the lungs. Bronchography, however, often shows bronchiectasis of a fairly severe nature. Invariably, because of the hemoptyses, these patients are treated for years at sanatoria.

The importance of bronchography and its vast field of usefulness have been briefly indicated in the various groups discussed above. Each group in itself could properly be the subject of an extended discussion. The subject has been presented in this fashion to indicate the prevalence of bronchial lesions and to emphasize their importance. In the earlier stages we are hoping by some simple measures, as pneumothorax, to arrest the progress of the disease to its hopeless final stage. With the aid of bronchography we are able now, at any rate, to detect the earliest lesions and to direct our energies toward the relief, if not cure, of the disease at a favorable time.

THE CHINESE LAUGH LAST

The western world has laughed for years at the Chinese use of toad poison as medicine. Now it begins to seem that the joke is the other way around. The *Lilly Physician's Bulletin* relates that during the last five years Dr. Chen and his associates have made an extensive investigation of toad poisons. The work was begun with Ch'an Su, a commercial preparation of the Chinese toad poison, sold even today at the drug stores. The Chinese have used this for centuries in toothache, gum bleeding, and so on.

For comparative studies, twelve different species of toads were collected from five continents. By chemical methods different active principles were isolated in pure form. They can be classified under five headings: ergosterol, epinephrine, bufagins, bufotoxins, and bufotenines. Epinephrine exists in large amounts. For example, *Bufo marinus*, the Jamaican toad, has more than four times the total amount of epinephrine in

man. Of course, in the toad it occurs in the skin glands, but in higher animals it is present in the adrenal glands.

Both bufagins and bufotoxins have a digitalis-like action. It was found that four of the bufagins are more powerful than ouabain, and ten toad principles more potent than digitoxin. Some of the bufotenines raise blood pressure to such a level that their activity is equivalent to 1/10 that of epinephrine. The toad apparently does not make use of its poison. It can be stimulated or scared by a dog, but it will not squirt poison. The poisonous glands are not essential to life. They can be extirpated and the toad continues to live indefinitely.

One of the touches of nature that "make the whole world kin"—or grin—appears in an Omaha medical journal. It reads: "Will the person who borrowed Dr. Prime's lantern some three years ago please return it so that Dr. Prime may use it for a while.

PROGRESS IN THE DIAGNOSIS AND TREATMENT OF PERNICIOUS ANEMIA

ELLERY G. ALLEN, B.S., M.D.
SYRACUSE

The years following Minot and Murphy's announcement¹ of a successful dietary régime for a previously fatal disease have been followed by an amazing and confusing literature on pernicious anemia. Not only have methods of treatment changed rapidly for the better, but clinical and laboratory studies have become so refined and improved that each passing year has given us more exact methods for diagnosis. Comparing the diagnostic and therapeutic data available and generally utilized in 1927 to that of the present, one cannot help but marvel at the tenacity of physicians in their tireless effort to bring still another disease under control.

The present article is necessarily but a brief résumé of some of our present-day diagnostic and therapeutic conceptions of the disease. From the general clinical aspect pernicious anemia presents several new points of view, possibly little appreciated in the years when the profession was, by reason of poor prognosis, less anxious to detect the condition. It now takes the attitude that all cases of anemia should be thoroughly investigated, irrespective of age, and the presence of other obvious disease entities. It is well known that pernicious anemia may occur in patients under 30 years of age. Occasionally it is detected in patients well beyond the allotted span of life, and all do not have grey hair and blue eyes. Again, another definite disease such as myxedema,² gastric carcinoma,³ syphilis, or arteriosclerosis in the aged may be the snare and delusion that prevents one's appreciating that true Addisonian anemia may also, in a given case, be present.

In this section of the country we rarely see a macrocytic blood picture except in pernicious anemia, gastrointestinal malignancy, cirrhosis of the liver and in long continued gross dietary deficiency, although it has been pointed out by Minot and Castle⁴ that "in any type of anemia, due to defective blood formation macrocytosis may be present, and it even occurs

occasionally in hemolytic jaundice." The anemia of gastric carcinoma is more frequently of a microcytic type, especially if the neoplasm is bleeding, although occasionally there is evidence of a hyperchromic⁵ or normochromic anemia. Despite these facts, the absence of increased blood destruction and positive x-ray evidence of neoplastic disease should serve to differentiate gastric new growths from pernicious anemia, even though the malignant case shows a macrocytic anemia. A further important point must be considered: It is well known that gastric carcinoma and pernicious anemia may coexist, and that in the same patient one or the other disease may appear first.³

Numerous observers⁶⁻¹² have recently pointed out that macrocytic anemia may be present in certain cases of cirrhosis of the liver. Cases we have observed have shown either a microcytic, normocytic, or macrocytic blood, similar in this respect to the situation in gastric carcinoma.

Although one must consider the diagnosis of cirrhosis of the liver in any case of anemia, he must appreciate, as was stressed by Fellingner and Klima,⁷ that the blood count is normal in early cases of hepatic cirrhosis and that, as the disease progresses, hypochromic anemia may be followed by hyperchromic.

The neurological manifestations of the disease, although usually fairly characteristic and involving the posterior and lateral tracts, or both, are often so atypical that one is indeed pressed to differentiate from central nervous system syphilis, multiple sclerosis, and peripheral neuritis. It has been pointed out by Russel, Batten and Collier,¹³ Hunt,¹⁴ and Grinker and Ernestine²¹ that the neurological symptoms may precede the anemia; again¹⁵ that the patient may present no symptoms or signs pointing to nervous system involvement, yet post-mortem lesions of the cord are found; also that the picture may be of the tabetic type.

The question of peripheral neuritis occurring in pernicious anemia has been much debated but there is some evidence to indicate that it may occur^{14, 15, 16}. It is not generally appreciated that clinical evidence of spinal cord changes has been noted in more than 80 per cent of a large group of carefully studied cases^{21, 22}. It is possible that this lack of appreciation has been partially due to our anxiety to relieve the patient of his anemia as quickly as possible, being less concerned about the indefinite nervous symptoms.

The more recent developments in hematologic technic have added greatly to our knowledge of diagnosis and prognosis. By means of the hematocrit and ocular micrometer, it is possible to estimate indirectly and directly the size of the red blood cells, thus differentiating the macrocytic, normocytic and microcytic anemias, one from the other. It is our impression that studies directed toward the estimation of the volume index and mean corpuscular volume are more to be relied upon than most color index calculations. This statement is made first, because of the common experience that rarely can two observers read a hemoglobinometer at the same figure, secondly, the majority of hemoglobinometers are based on a different standard as representing 100 per cent hemoglobin.

The determination of the icteric index, Van den Bergh reaction,²³ and urinary urobilinogen in hematologic relapse are valuable, although frequently neglected procedures. In a series of 35 cases of pernicious anemia taken from the University Hospital records, the icteric index was increased in 25 of 26 cases in which it was estimated, it is also significant that in almost every instance one finds a positive indirect Van den Bergh and an increase in urobilinogen in those patients presenting an increased icteric index.

The estimation of the reticulocyte count is of extreme importance, in order that the effect of initial therapy may be prognosticated. In our untreated cases in relapse, the reticulocytes have numbered between 0.1 and 1.1 per cent, the majority revealing percentages between 1 per cent and 5 per cent. After the first few days of treatment, before the erythrocytes have increased to any extent,

these vitally stained cells have, in some instances, increased to levels in excess of 30 per cent—a definite indication that hematologic improvement is shortly to follow.

Who among us has not been bewildered by the variety of preparations offered as a better product than its competitor for the treatment of the disease? Calf's liver, pig's liver, fetal liver, horse liver, liver extract by mouth, subcutaneously, intramuscularly and intravenously, autolyzed liver, pig's stomach (with or without iron), combinations of liver extract and desiccated pig's stomach, and so on, *ad infinitum*.

Each worker in the field has, by experience, chosen, after trial, an effective remedy, and we shall but mention a plan of treatment, similar to the one advocated by Murphy,¹⁰ that in our hands has been uniformly successful in the treatment of the anemia. In relapse 6 c.c. of concentrated liver extract is given intramuscularly, after estimating by a half c.c. intramuscular dose, whether or not the patient is sensitive. If no fever or reaction results in 2 hours following the half c.c. intramuscular injection, the remainder of the 6 c.c. (representing 200 grams of liver) is introduced intramuscularly into the gluteal region. A week later 3 c.c. is given intramuscularly and thereafter the same dosage once weekly. A point of some interest is that the single, intramuscular 3 c.c. dosage of concentrated liver extract, given but once weekly, probably represents more available potent material than the patient would obtain, were he to eat one pound of liver each day.

Other treatment, often a valuable adjunct, is Dil. HCl, for those patients presenting digestive disturbances particularly diarrhea. In certain cases, after rapid regeneration of erythrocytes, the red blood count and hemoglobin fail to increase satisfactorily after a level of $3\frac{1}{2}$ to 4 million is reached. In such instances the color and volume index is occasionally found to be below 1.00 and it is at this point that the administration of adequate inorganic iron by mouth appears to be of distinct benefit in aiding a further increase in the hemoglobin and erythrocyte values. Satisfactory preparations of iron are Ferric ammonium citrate 6 grams a day,

reduced iron 1 to 2 grams a day, or ferrous sulphate,^{17, 18} 9 grains a day. It is felt that a satisfactory response is obtained if the red cells increase $\frac{1}{2}$ million a week, although these figures vary greatly in individual cases, the response being greater in those patients having the lowest counts when treatment is instituted.

It is of some importance that the red blood count be maintained at a level of about 5,000,000 or more, as it would appear that such individuals are the least likely to develop neurological manifestations. Once the desired red count and hemoglobin percentage has been attained, the intramuscular injection of 3 c.c. of the concentrated liver extract, given once in 3 or 4 weeks, is usually sufficient to maintain a satisfactory level, although some cases, particularly the aged, pregnant or lactating women, and those patients harboring infections, and so on, may require one injection a week; rarely a case may be maintained on a 3 c.c. injection administered once in 6 weeks.

Those cases presenting objective or subjective neurological symptomatology, have been treated weekly with 3 c.c. of the concentrated extract, and we are able to say that of the patients we have seen at the University Hospital and at the Free Dispensary during the past year, no case has failed to improve on this régime, and at least three, unable to support or transport themselves, have improved miraculously. One of these severely affected cases has had, in addition to liver treatment, physiotherapeutic measures for muscle relaxation. However, the one neurological case showing the greatest clinical improvement had no such physiotherapeutic treatment.

The question naturally arises as to what constitutes adequate treatment. In most instances the anemia is not a serious problem, if sufficient potent material is administered, and the real difficulty presented to the physician is the prevention or amelioration of neurologic complications. We are of the opinion that patients with red blood counts of 4 million are not adequately treated and it is well known that cases with red blood counts in excess of 4 million may occasionally develop serious, rapidly progressing neurological complications.

Meulengracht¹⁹ has declared that "the longer the hematologic features were controlled by liver and liver extracts, the greater was the incidence of myelopathy."

The experience of Minot and Castle²⁰ is emphatically the reverse of this dismal outlook. In more than 100 patients they have treated adequately with liver extract, no increase of existing lesions has occurred and no evidence of cord lesions has appeared for the first time.

Goldhamer²¹ and his associates, studying a large group of cases with neurological manifestations, have noted subjective improvement, irrespective of the type of adequate treatment, in about 50 per cent of their patients, and objective improvement in about 2 per cent.

A report by Grinker and Ernestine,²² read in 1933, held that "liver therapy is not efficacious in improving or preventing degeneration in the central nervous system . . . the majority of cases of combined degeneration of the cord develop rapidly at the onset and then progress slowly, no matter what therapy is employed."

Haden²³ is of the opinion that "the neurologic complications need never develop if the patient is co-operative and has been fully and continuously treated." Intensive therapy, he believes, will also ameliorate strikingly the neurologic symptoms after they have developed. He further states that "with intensive therapy the erythrocyte count should be well above normal. The volume of the cell is certainly the best index of the result of treatment. So long as macrocytosis of the red cells persist, the treatment is not adequate and the deficiency responsible for the disease is not fully met. I have yet to see a patient develop a neurologic lesion if the adequacy of treatment is judged on such a basis." Expressing a similar note concerning the necessity of adequate, continuous treatment, Murphy¹⁶ has pointed out that the "red blood cell level should remain preferably at or above 5,000,000 cells per cu. mm., and the cells themselves should be normal in size and shape. Although the occurrence of symptoms is an important indication of inadequate treatment, the absence of symptoms or a feeling of well-being is neither sufficient evidence that the blood is remaining

normal nor that the patient is in satisfactory condition to avoid progression of the nerve disturbances."

It is our opinion that every effort should be made to keep the erythrocyte count above the average normal figure and that more intensive therapy should be instituted the moment any symptoms or signs of neurologic involvement present themselves, irrespective of the red cell counts and hemoglobin levels. To date the patients we have treated, in the manner heretofore described, have developed no demonstrable neurological lesions for the first time, and all cases with already existing neurological symptoms have improved, at least subjectively.

Prior to the advent of liver extract for parenteral use, the cost of oral treatment for some patients, was almost prohibitive; in addition, the powdered and liquid extracts were not particularly palatable, although it may be said that a not unpleasant tasting desiccated hog's stomach preparation is now available. Parenteral liver extract has obviated the former difficulties of expense, the physician is sure of the dosage, and also that absorption will take place. The patient is not made responsible for eating liver, taking hog's stomach or liver extract, and the concentrated liver extracts such as we are now using, necessitate only infrequent injections. During relapse, or until the hemoglobin and red cells reach the normal figure, the cost of the liver extract, is about ninety cents a week (1 ampoule). The cost of maintenance dosage averages approximately thirty cents a week (1 ampoule in 3 weeks). Thus it is obvious that such a plan of

treatment is by far the most inexpensive program available today, and at the same time, it is believed, the most satisfactory.

Summary and Conclusions

(1) A review of the more recent diagnostic and therapeutic conceptions of pernicious anemia has been presented.

(2) Thorough clinical and hematologic investigation should be made in all conditions in which anemia is found, because of the not uncommon coexistence of pernicious anemia and other disease entities.

(3) The physician's greatest responsibility is the prevention or amelioration of nervous symptoms.

(4) The author is of the opinion that neurologic manifestations need not appear if patients are adequately and continuously treated, and that subjective improvement may be expected in the large majority of cases already showing nervous system symptomatology.

(5) It appears that concentrated liver extract, administered by the intramuscular route, is the most satisfactory method of treatment.

Acknowledgment

This study was aided by a grant from the Hendrick's Research Fund of Syracuse University Medical College. The author is also indebted to Dr. E. C. Reifstein, under whose direction these studies were conducted, for the privilege of studying the cases included, and for his many helpful suggestions.

STRIKING RESULTS WITH SYNTHETIC VITAMIN C

Synthetic vitamin C, called ascorbic acid, is producing unexpected conquests of disease, the British Association for the Advancement of Science was informed by Prof. A. Szent-Györgyi, the Hungarian chemist who played a major rôle in the artificial manufacture of this important vitamin, according to a report in the *Diplomate*, organ of the National Board of Medical Examiners. A certain kind of hemophilia, the mouth disorder known as pyorrhea, certain forms of hemorrhagic nephritis, and several other diseases against which medicine was helpless, are seemingly being cured by ascorbic acid. It does not cure hereditary hemophilia, the report says.

"This is the more striking since these pathological conditions have not been thought to be connected with lack of vitamin," Professor Szent-Györgyi explained. "These curative effects suggest that humanity is suffering much more gravely from a lack of vitamin C than has hitherto been supposed."

Disfiguring colorations of the skin brought on by illness are also made to disappear by ascorbic acid. The skin of patients with Addison's disease can be bleached out again by the use of this substance.

The complete exploration of vitamin C was accomplished in record time. In the short space of two years vitamin C has been identified, its chemical structure determined, and it has been made synthetically in the laboratory. The pure, highly concentrated vitamin C acid has been made

available for industry and medicine. Hungary—represented by Professor Szent-Györgyi, who is director of the Institute of Medical Chemistry, Szeged University—Switzerland, England, and other countries have worked together through their scientists in this great chemical conquest. "It is pleasant to note that this unparalleled advance is due entirely to the closest and friendliest international collaboration," Professor Szent-Györgyi said as he spoke before British scientists.

It is predicted that the rôle of ascorbic acid in life may be even more important than is now realized, for there seems to be no cell-life in higher organisms without ascorbic acid.

Young doctor (to impatient creditor)—If you must come every few days with your account you might at least bandage your head so that people will take you for a patient.—*Vart Hem.*

"What are you giving your cows now in the way of galactagogues?"

"Oh," replied the milkman, "their sustenance is wholly of vegetable origin, rich in chlorophyll and opulent in butyrateous qualities."

"Let me have a pint," said the professor.—*Colorado Medicine.*

FOREIGN BODY IN THE HEART

Report of a Case with Retention of a Large Needle with Recovery

GEO. L. FAIR, M.D.,

Visiting Surgeon Kings Park State Hospital

OYSTER BAY

Cases of successful removal of missiles and penetrating instruments from the heart have been on record for many years. Fischer¹ in 1868 collected from all available previous literature 452 cases of heart and pericardial wounds. He gave a very complete history of the subject and an extended description of the anatomico-pathological lesions met in the different cases. He showed that wounds of the heart are not constantly fatal and sought to establish the symptoms and diagnosis as well as to show the therapeutic treatment of his times.

The first case of successful recovery following the lodgement of a needle in the heart is described by Fischer as that of Gerard's in 1834. The needle passed through the sternum into the wall of the right ventricle. The patient lived six years the cause of ultimate death not being stated. Fischer compiled a large number of instances of healed wounds of the heart containing foreign bodies carried about for years without apparent disability.

Thirty years later Loisson² collected 61 cases which had been observed in that interval. He divided his report into wounds caused by needles (23) and those caused by penetrating instruments (38). His descriptions of the needle injuries are of particular interest in connection with the case to be described. The mortality was 14 of the 23 cases or 61 per cent. None of these was due to infection. In none of Loisson's cases was the wound of entrance through the sternum as in Fischer's case or as in the one to be reported here—but all were through an intercostal space. The needle was fixed in the left ventricle (in 3 cases), right ventricle (2 cases), left ventricle and mitral valve (1), right ventricle and tricuspid valve, right ventricle and intraventricular septum and right auricle 1 each. In two cases where the point was protruding it eroded the endocardium

and the auricular wall of the intraventricular septum situated near it. In another case the diaphragm was eroded and perforated. In two other cases the repeated rubbing movement caused a hole in the right ventricle.

The cases in Loisson's series which recovered where the needle could not be removed were three in number. In Foy's³ case in 1887, an inebriated medical student plunged a needle into his heart. The pericardium was opened and the eye of the needle seen at the surface of the right ventricle. The muscle was superficially incised. It buried itself further with each systole and could not be reached. The patient recovered completely without cardiac symptoms. It is not stated how long he lived. In Macdougall's⁴ case in 1895 a girl of 15 accidentally plunged a needle into her breast in the third left intercostal space a half inch from the sternal border. The needle made excursions synchronous with the pulse and disappeared under the skin. An incision was made over the extremity of the needle seen through the skin. It buried itself and was not recovered.

There were no symptoms following this and the patient remained well "a long time after the accident." In a case of Stelzner's⁵ in 1887 a young man forced a needle into his heart while intoxicated. At the end of twelve hours he had pains, dyspnea, and intense sensation of friction over the apex of the heart. He collapsed in 36 hours. A part of the fifth rib was resected, the pleura being accidentally opened while incising the pericardial sac. The needle was found penetrating the right ventricle transversely. Several ineffectual attempts were made to extract it. The patient developed pneumothorax and pleural effusion. All symptoms progressively improved.

The earliest case of successful removal of a needle from the heart dates back to

Fig. 1. This film was made immediately after the insertion of the needle on April 26, 1934.

1835. In case No. 40 of Fischer's series, O'Connor⁶ reported a case of a needle insertion directly into the second interspace but the report is uncertain whether it was situated in the lung or heart. There were signs of "acute inflammation of the heart" and increased respirations, which subsided when the needle was removed. Callender,⁷ however, claims that his case report in 1873 was the first authentic one. A pewterer, aged 31 years, ran a needle through the fifth left interspace in a fight. The skin overlying the entrance was incised and the needle withdrawn. He had a successful recovery.

In 1888, Foot⁸ reported the case of a child brought to him at Meath Hospital with a needle in the heart, accidentally plunged there by the mother. The eye of the needle moved with the pulse. It was withdrawn by a rotary motion to lessen chance of hemorrhage. There were no further ill-effects. Turner⁹ in 1896 gave a report of successful removal of a needle in the heart of a two-year-old child by rotary traction through a skin incision. No harmful effects were noted. Prior¹⁰ in 1897 gives the case of an asylum

patient, aged 43, in Glasgow, who pushed a wire 4" by 3/16" with suicidal intent through a point 1 3/4 inches below and 1 inch internal to the left nipple upwards and inwards. After removal, aside from some subcutaneous emphysema, a pneumothorax of short duration, and a week's febrile reaction, he recovered and was normal afterwards.

This case is presented because it adds to the records another case of successful recovery with retention in the heart of a large foreign body, a laundry needle, after failure in an attempt at its removal.

Report of a Case

Mr. O. E. was admitted to the King's Park State Hospital on August 16, 1932. He was then 59 years of age, a German-American, occupation, bookkeeper. His diagnosis was involutional melancholia.

Previous History: He was committed to the hospital following two suicidal attempts, apparently from despondency, being unable to obtain employment and without money. Shortly after his admission he brightened up considerably, took an interest in his surroundings, although at intervals he was inclined to be depressed and com-

Fig. 2. Lateral view, April 26, 1934

plained of a whispering voice. Because he showed considerable improvement and did not evince any suicidal tendencies, he was placed in the laundry of the hospital to work.

Present Illness: On April 26, 1934, at about 1:30 P.M. the patient made an attempt at suicide by thrusting a needle into his heart. The needle was described as being three inches long and about one-eighth inch in diameter, used to mend large canvas laundry bags. When discovered he was in moderate shock, pale, skin clammy, and pulse slow and feeble, rate 60, respirations 18 per minute. He did not complain of pain in or over the heart but wanted to be left alone to die.

Physical Examination April 26, 4.00 P.M. Pulse 60, temp. 98.8, resp. 18. The patient, an adult German-American of middle age, was apparently in previous good health. His weight was 172 lbs. The skin was cold and clammy, the pulse 60 in rate and feeble. Respirations were slow, 18 per minute. There was no cyanosis but marked pallor. There was no evidence of peripheral vessel arteriosclerosis. The chest was normal in size and outline, and the breath sounds were everywhere normal. The heart was not enlarged to percussion; the apex beat was feebly palpable in the fifth left inter-space 9 cm. from the midsternal line. The heart sounds were faint but normal, not muffled and no adventitious sounds could be heard. Bloodpressure at time of operation was not taken. Urine was negative.

Special Condition: There was a puncture wound about 3 mm. in diameter over the center of the last segment of the manubrium sterni just above the xiphoid process. No foreign body could be felt beneath this wound. There was no fresh oozing of blood externally.

Preoperative X-Ray: Roentgenogram of the chest on the day of operation taken one hour before operation showed a large needle within the pericardium and imbedded in the heart (Figures 1 and 2). As will be noted in the accompanying x-ray, the head of the needle lies close to the sternum. There is no apparent hemopericardium present.

Operation April 26, 4:30 P.M.: As the eye of the needle seemed by x-ray to be easily accessible, there was danger of the wound entrance in heart becoming enlarged from constant motion of the needle, and as the patient's condition was grave it was decided to attempt to remove it at once.

Under light ether anesthesia a transverse incision from midsternum outwards over the left fifth costal cartilage for a distance of 3" was made. The mesial $1\frac{1}{2}$ " of this

Fig. 3 View on third postoperative day, showing position of needle and development of pleural effusion

cartilage was divided by a costotome and disarticulated from the sternal junction. The left internal mammary artery was ligated. The pericardial sac was opened for a distance of $\frac{3}{4}$ " transversely through the opening. The pericardial cavity and the accessible ventricular area was thoroughly explored digitally but no needle could be felt. It was inferred that the ventricular contractions had carried it well into the ventricular muscle. The patient's condition did not warrant an incision into the heart muscle, particularly when the eye of the needle could not be felt or the wound of entrance into the right ventricle identified. There was a fairly profuse flow of blood from near the apex of the heart. The left pleural cavity was inadvertently opened. The increased respiratory movements resulting made it impossible to close the pericardial opening. As fresh blood was still escaping from the ventricular opening, the lower anterior portion of the pericardial sac was packed with one-inch iodoform gauze. The wound was closed with the end of the gauze for a drain, using No 2 chronic catgut between the pectoral muscle and perichondrium of the sixth costal cartilage, silk-wormgut reten-

Fig. 4. Lateral view of chest with 2-second exposure, showing excursion of tip of needle during heart beats. Taken on 25th postoperative day.

tion sutures through the same, and silk for the skin.

Postoperative Course: The patient recovered quickly from the shocked condition but ran a persistent temperature 99.4 to 102° following removal of the packing on the first postoperative day, with drainage of pus from the pericardotomy wound from the fourth postoperative day.

The x-ray (Figure 3) on April 29 showed an extensive left sided pleural effusion. Aspiration of May 15 showed thick pus with a growth of staphylococcus aureus on culture. On May 16 a thoracotomy under local anesthesia was done, removing a part of the ninth left rib posteriorly. This empyema slowly improved but cessation of drainage has now ceased, his temperature having been normal for the past month.

Present Condition: At no time postoperatively did the patient complain of cardiac pain. The pericardotomy wound is now completely closed and epithelialized. The heart is moderately enlarged to the left, measurements of the area of cardiac dullness being normal for the right border and on the left being 2.0, 6.5, 10.0, and 11.0 cm. in the second to fifth interspaces,

respectively. He has no dyspnea or cyanosis on being up and around. The heart sounds are normal and no pericardial friction rub can be heard. The left lung is apparently normally expanded and the breath sounds clear. His weight after dropping to 131½ lbs. on May 14 is now 151 lbs. His pulse is 68 to 70 at rest and 88 to 90 seated. His temperature and respirations are normal.

Position of Needle by X-Ray: Comparing x-ray appearance in Figure 4 with that in Figure 5 it will be seen that the needle has not moved up in two months' time from the postoperative situation. Figures 4 and 5 show the head of the needle intramuscularly having moved inward from the position in Figure 2 where it seemed in the pericardial sac. To consider the pulse rate of 90 in the picture in Figure 4 it is seen that the head of the needle is fixed apparently by adhesions at the apex, and the shaft and point move in and out with each systole of the right ventricle; this being a 2 sec exposure by a portable x-ray, the movement is shown through approximately

Fig. 5. Lateral view on 96th postoperative day, with one-tenth second exposure, showing relatively same position as in Figure 4, 71 days previously.

three systolic contractions. Figure 5 shows a lateral view of the thorax with a much better view of the needle by a stationary x-ray with 1/10 sec. exposure. At no time have we been able to see the needle by fluoroscopic examination with stationary x-ray machine of the usual penetration for hospital use. Yet Villéon¹⁰ has devised a technic for removal of foreign bodies under fluoroscopic control.

Conjecture as to Ultimate Fate of the Needle. Bland-Sutton¹¹ in 1919 cited a number of war cases of bullet wounds with missiles retained and classifies the possible outcome as follows:

A bullet loose in the cavity of the heart is swirled in the blood current. Some have been watched fluoroscopically and may have an elliptical movement with a definite axis. They may be expelled into the bloodstream at any time with symptoms of embolism.

(a) A bullet in the right ventricle may be ejected and produce fatal pulmonary embolism. Such a case has been known to survive 12 days and is recorded by H. J. Fry¹¹ at the War Office Collection, London.

(b) A bullet in the left ventricle may be driven into a systemic artery and produce ischemia. Schloffer¹² in 1903 reported a case of lodgement in the axillary artery with later removal and recovery. Cases of lodgement in the common iliac artery are reported by O'Neill¹³ and Bland-Sutton.¹¹

Fischer¹ in 1868 compiled a large number of instances of healed wounds of the heart containing foreign bodies carried about for years without apparent disability. Turner¹⁴ in 1881 reported a case of a soldier who died of other causes with a bullet imbedded in his heart from a wound 6 years before. On the other hand, Viller¹⁵ in discussing the indications for the removal of foreign bodies cites a case of Professor Tillaux where an iron rod 16 cm. long, left in the heart, caused death a year later by penetrating the posterior wall of the ventricles and penetrating the right lung.

Now in the case which the author has described it would seem that the patient has a reasonable chance of no further trouble. Comparison of plates in Figures 4 and 5 shows no further migration of the needle that is apparent. Any erosion

by the point of the needle as described by Loisson² here would seem to be harmless, except possibly to produce some injury to the endocardium of the tricuspid valve or intraventricular septum.

Procedure in Similar Cases

There seems no doubt that in this case attempted removal immediately upon discovery was the procedure of choice. Unfortunately some 2½ hours elapsed before this case was discovered, x-rayed, and the author summoned to attend. During this interval the needle had been in the process of retraction into the heart by the systolic contractions. When first seen by a hospital physician it was not palpable beneath the skin. In the interval between his x-ray and surgical intervention (about one hour) it had been further retracted so that it could not be reached without an incision into the ventricular muscle.

Many surgeons are of the opinion that with stab wounds by long slender objects remaining "*in situ*" they should be withdrawn at once (see Rehn;¹⁶ Terrier and Raymond¹⁷) after careful exposure of the wound, and the patient afterwards carefully observed for signs of "heart tamponade." In Loisson's² 23 reported cases there were 14 deaths following surgical treatment, none of which, however, was due to infection.

The best policy as to treatment and grouping of such cases in the literature, in such emergencies seems to be that of Delorme¹⁸:

(1) Where grave manifestations are present, cases with cardiac pain, suffocating crises, cardiac irregularity and palpitation, whether intracavitary or intramuscular, all require operation at once.

(2) Where the symptoms are less alarming and tolerable and there is definite hope that the missile may become fixed and encysted, there is every reason to wait even though there is danger of transportation to another area where its lodgement may cause untoward and dangerous sequelae.

(3) In those cases where the symptoms are negligible but in which the missile lies free in the chamber of the heart the danger from migration or irritation (especially if the foreign body is rough) is too obvious. Removal here seems to be the

proper course. In the left ventricle, however, if it were smooth Delorme would not intervene until it had lodged in another cavity; if rough (e.g., a fragment of iron), he would explore for it.

Summary

(1) The first reported cases of recovery with a retained needle in the heart are those by Gerard, 1834; Foy, 1887; Macdougall, 1895; Stelzner, 1887.

(2) The first reported cases of successful removal of a needle from the heart are those of O'Connor, 1835; Callender, 1873; Foot, 1888; Turner, 1896; and Prior, 1897.

(3) A case is added to the literature by the author. It concerns a man, 60, patient in a mental hospital, who forced

a large-size needle into the wall of the right ventricle of his heart. Operation within three hours of the act found the needle inaccessible, in the heart muscle, due to retraction by systolic contractions. Although recovery was complicated by suppurative pericarditis and empyema, the patient is alive and well at seven months with the needle still in the right ventricle without apparent embarrassment.

(4) The fate of foreign bodies in the heart is discussed as well as conjectures as to the probable outcome in this case.

(5) The need for prompt attempt at removal in similar cases is emphasized.

(6) The generally accepted grouping of cases with policy as to treatment as advised by Delorme is given.

ANOTHER MEDICAL HERO

If "peace hath her victories no less renowned than war," she hath her heroes as well. Another in the illustrious list risked his life for science in November last. We are told in the December, 1934, *Archives of Internal Medicine* the personal and physical reactions of A. W. Blair, M.D., of University, Alabama, who deliberately arranged to be bitten by a female spider *Lactrodectus mactans*.

At 10:45 A. M. he sustained the bite; at 11:18 A.M., pain extending up arm and chest; 11:55 A.M., definite epigastric pains; 12:00 noon, fall in blood pressure and weak pulse; 12:45 P.M., agonizing pain in abdomen, back and legs, taken to the hospital; 1:00 P.M., in profound shock, pulse uncountable; 1:15 P.M., in excruciating pain, pulse 150, labored respirations.

November 13: An evening and night of extreme suffering in spite of morphin, face swollen, eyes red, watery, albumen in urine.

4:00 P.M., pain, flushed, swollen face, tongue coated, fetid breath, nauseated, tense abdomen.

November 14: Restless night—rheumatoid pains in leg, sweating, and weakness, abdomen tense.

November 15: Home in ambulance.

November 20: All symptoms cleared up.

These few extracts, remarks *California and Western Medicine*, impart but a meager picture of what occurred in this eight-day period recorded in five printed pages of clinical notes. They do, however, add one more name to the roll of heroes for science.

"Do you guarantee results in your nerve treatment?" asked the prospective patient.

"I do," replied the specialist. "Why a man came to me for nerve treatment, and when I had finished with him he tried to borrow \$50."—*Colorado Medicine*.

County Societies

Bronx County

The Bronx won out over Queens in the anti-diphtheria immunization contest which closed February 9, according to Dr. John L. Rice, Commissioner of Health. The Bronx had 344 more immunizations of children under the age of six years than had Queens, and as a result, the Bronx County Medical Society is to be presented with a silver trophy by the Chamber of Commerce of the Borough of Queens.

In a similar contest conducted by the Department of Health in the Bronx and Queens in 1933, Queens had the lead over the Bronx by a margin of seven immunizations. At that time the Medical Society of Queens County was presented with a cup by the Bronx Chamber of Commerce. While the campaign ran for 17 weeks, the Christmas vacation really took out two weeks, making the running time 15 weeks. In that time 11,062 children under six years of age were immunized in the two boroughs, 5,703 in the Bronx, and 5,359 in Queens.

During the entire campaign 17,980 children of all ages were immunized in the two boroughs; 9,535 in the Bronx and 8,445 in Queens. This was an average of approximately 1,200 for the two boroughs each week—636 for the Bronx and 563 for Queens. For the entire year of 1934 immunizations in the Bronx averaged 346 a week, as against 212 in 1933, and Queens averaged 316, as against 182 the year before. The difference between the weekly average and the average of immunizations during the campaign for both boroughs was an increase of 538 for both boroughs, a gain of more than 54 per cent.

The outstanding and gratifying feature of the campaign was the fact that the majority of the children immunized, 11,062 were under six. This means 62 per cent, one of the highest marks reached for preschool children in any previous campaign in those boroughs.

Delaware County

An earnest discussion of bills at Albany affecting the medical profession was a feature of the quarterly meeting of the Delaware County Medical Society on March 19, reports the secretary, Dr. William M. Thomson, of Delhi. He adds that "the Society has been very prompt and energetic in corresponding with our Senator and Assemblyman from this District, and I am happy to report that they have been very

co-operative with us." Dr. Carl Schumann, of Delhi, was unanimously elected to membership.

Erie County

The Buffalo ERB board has under consideration the plan of the Medical Society of the County of Erie to provide medical care for welfare through their family physicians, Dr. John L. Hoffman of Kenmore, chairman of the Society's committee on economics, reported at the society's March meeting.

Dr. Hoffman declared it to be the opinion of his committee that there are "a large number of persons who do not want the impersonal services of the clinics." Under the Society's plan, physicians would be reimbursed by the Department of Social Welfare at the rate of \$2 a house call, \$1 an office call, and \$25 for an obstetrical case, the rates being paid in Erie County.

The city officials of Buffalo have been sharply called to account by the State Department of Health for polluting the Niagara River with sewage. "The discharge of untreated sewage by the city of Buffalo," declares the Health Commissioner, has caused a "serious and dangerous menace to health." The cities imperiled are Tonawanda, North Tonawanda, Niagara Falls, Lockport, Lewiston, Youngstown, and Fort Niagara which derive their public water supplies from the Niagara River. An epidemic of thousands of cases of diarrhea at Niagara Falls was attributed to this cause, and the menace is said to extend even to towns on Lake Ontario and along the St. Lawrence River.

Kings County

An old-time German street band started the festivities on the evening of March 14 at the Hotel Granada in Brooklyn when more than 150 physicians, lawyers, clergy, nurses, patients, and other friends gathered at a dinner in honor of Dr. George H. Reichers, chief surgeon at the Bushwick Hospital, who has just completed 22 years of service there. The band marched into the banquet hall blaring lustily and lingered to render choruses in which all the diners joined. Later a song, the words of which were composed especially for Dr. Reichers, was rendered by the diners to the air of "The Man on the Flying Trapeze," to the obvious delight of the guest of honor. The speeches were a mixture of serious tributes

and humorous badinage. A shout of laughter greeted Rev. Dr. Genns when he said he had lived 30 years next door to Dr. Reichers and still loved him.

Concerned over what it describes as "the lost art of prescription writing," the Medical Society of the County of Kings announces a course on the subject for its members at the Brooklyn College of Pharmacy. Four lectures will be given by Dr. Frederick Schroeder.

Dr. Alec N. Thomson, director of medical activities, said the society had become alarmed at the increasing tendency of physicians to prescribe patent medicines. The result, he added, had been that druggists had suffered and physicians had come to rely too much on the products of pharmaceutical manufacturers.

The need for a course on prescription writing was presented recently to the society in a report by Dr. Thomas F. Nevins, chairman of a committee considering pharmacy and dispensing practice.

"The pharmacist," he said, "in many instances now being forced to become a soda-water dispenser and restaurant keeper, has a grievance with our profession which is just and cannot be ignored. The lost art of prescription writing, and the ease with which 'patents' are provided for us by the pharmaceutical manufacturers, have led many of us to prescribe these frequently and thoughtlessly without regard to what it would do to the pharmacist and to ourselves.

"It has forced the pharmacist to stock his shelves with all sorts of products many of which move rarely, if at all. It has taught the public the noble art of self-medication. We must admit that we have played a very active part in popularizing this art to our own undoing."

Dr. Nevins contended that the proper prescribing of numerous useful drugs would overcome the tendency toward self-dispensing and would restore the pharmacist to his proper place in medical life.

It is expected that several hundred physicians will attend the lectures.

Livingston County

Buildings of the new State Tuberculosis Hospital at Mount Morris will probably be turned over to the State about the middle of April, according to the State Health Department's current bulletin. In charge of the institution will be Dr. N. Stanley Lincoln, formerly clinic physician in the Department's Division of Tuberculosis, who has been transferred from the superintendency of the Herman M. Biggs Memorial Hospital

in Ithaca to the corresponding post in the Mount Morris Hospital.

Monroe County

All the valuable advice is not given by famous medical men in their set speeches. For instance, when Dr. Alfred W. Adson, chief neurologic surgeon of the Mayo Clinic at Rochester, Minn., visited the Rochester (N. Y.) Academy of Medicine in March to speak on his specialty, he told a newspaper photographer that fat men shouldn't sit down to have their pictures taken.

"Sit a fat man on anything soft," he explained, "and his body immediately pushes as much fat as possible up to his chin."

A hard chair was promptly secured for the picture.

More than 200 pupils of the Fairport schools have received the tuberculin test, which was given to all students who have lost weight during the past year, and whose parents gave their consent.

Dr. George Price, health officer and medical inspector of Fairport schools and chairman of the communicable disease subcommittee of the Monroe County Medical Society, was in charge of the testing.

An annual joint meeting of the Rochester and Syracuse Academies of Medicine is being considered. If the idea has sufficient approval, a meeting will probably be arranged for late Spring or early Fall. Rochester has been invited to go to Syracuse for the first meeting, the Rochester Academy to furnish the speaker.

Nassau County

The growing number of free clinics, over which medical men have no control, are becoming a menace to the best interests of both doctor and patient in Nassau County, and the profession feels that the best service can be given through clinics maintained by the doctors or by "public health hours" at each doctor's office. The County Medical Society has found that in many of the free clinics there is no attempt to determine the financial status of an individual applying for free service; that many could pay nominal fees to the family doctor, or a partial fee, and, if destitute, could be carried by the doctors as a confidential charity case. An additional thought expressed by the committee was that in some cases actually paying patients of doctors are taken away from them and referred to free clinics. Only those types of cases should be referred to a public clinic which no doctor

wants or which no one doctor is equipped to handle the committee maintained.

The committee urged at a meeting of the County Society on February 26 that public health clinics be condemned because they are unwarranted, because the doctors have drawn up a program for their operations in hospitals and because the doctors are ready and willing and have agreed to perform all services demanded of a clinic in their own offices.

The committee recommended that any doctor servicing a disapproved public clinic be considered as a violator of the ethics provisions of the American Medical Association. This in effect would exclude a doctor from good standing in any medical society in the entire nation.

Under the plan adopted by the society those desiring clinical attention will call at the office of their family or neighborhood doctor. If the patient is able to pay he will be charged the usual fee and if further clinical attention is required, will be referred to a properly supervised clinic by the doctor.

If the patient is unable to pay the full fee arrangements have been made for the payment of a partial fee. If the patient is unable to pay any fee such as a welfare case, he or she will be given the same attention as the paying patient and the doctor will either accept the case as his own charity case or secure a medical relief authorization.

The resolution adopted by the Society released in full by Dr L. H. Bauer of Hempstead, chairman of the medical economics committee follows: "Resolved, that the Medical Society of the County of Nassau, having outlined a proper and inclusive procedure for the handling of indigent cases in this county, disapproves of any of its members taking part in any clinic not specifically recommended by this society and that it will consider any member who violates this resolution as not acting in accordance with the tenets of the ten point program laid down by the American Medical Association at the 1934 session of its house of delegates and by the council of the New York State Medical Society on December 13, 1934. The report is unanimously approved by the medical economics committee. (Signed) Dr Louis H. Bauer, Dr Julian Dean, Dr E. K. Horton, Dr W. F. Lewis and Dr P. A. Williams."

This resolution was adopted unanimously by the Society. Dr George A. Newton of Freeport, president, announced that the members of the Society are prepared to assume the responsibilities laid down in the resolution at once.

It is believed that the action of the Society sounds the death knell of public health clinics of all varieties which are conducted by laymen without medical direction or supervision in Nassau County. In other States and Counties in the Midwest where similar procedure has been taken "free" clinics have been wiped out of existence.

New York County

Telling shots for and against socialized medicine were fired by some of the heavy artillery of the State and County Medical Societies at the New York Academy of Medicine on March 28. That socialized medicine is the next logical step in our national program goes without saying," declared Dr Morris Rosenthal, Director of the Bureau of Compensation Insurance of the County Society, and he added roundly that "if the medical profession is opposed to state medicine there is very little it can do about it," and "the profession will have to take the part assigned to it with as good a grace as may be when it is offered."

On the other side, Dr Frederic E. Sondern, President elect of the State Society, remarked that if experience proved that compulsory sickness insurance meant adequate medical care for all the people, then the physicians "would be the loudest advocates of that system" but they oppose it "because regimentation and by control of professional services are known to be fatal to progress and inevitably lower the quality of the service." Sickness among the workers of England and Germany, instead of lessening or even standing still "has almost doubled in England in the 24 years and trebled in Germany in the 50 years under this system of medical care." Dr Haven Emerson of Columbia, too, agreed that there is nothing to show that the new plans suggested "would improve the quality or increase the quantity of medical care beyond present performance."

Why socialized medicine fails was pointed out by Dr Samuel J. Kopetzky, Speaker of the House of Delegates of the State Society. In Europe under this system "the doctor is so poorly paid that he must see about 50 patients a day to earn the most modest livelihood." He makes hasty diagnoses and hands out stock prescriptions and in time becomes incapable of accurate diagnosis and correct treatment. In fact the poor here get far better medical care than the beneficiaries of socialized medicine in Europe. "The human body is not a motor-car—and large scale industrial methods will not heal its ills."

First steps toward putting into actual

operation the long-discussed plan of group hospitalization insurance for earners of wages and small salaries, assuring them of hospital care in the event of illness in return for a premium of 90 cents monthly, are announced by David H. McAlpin Pyle, president of the United Hospital Fund.

The plan is being installed by the Associated Hospital Service of New York, a non-profit corporation, which has sent invitations to 140 hospitals in the metropolitan area to join the project. The hospitals are now acting on these invitations and soon, according to Mr. Pyle, the hospital service group will begin solicitation of annual memberships in the insurance plan among employed groups.

Under the plan, employees would authorize their employers to deduct 90 cents a month, or \$10 a year, from their pay. This would constitute their full subscription for one year.

Each such subscriber, Mr. Pyle explained, would be entitled to three weeks of semi-private hospital care during the contract year without further charge.

To gain admission to a hospital, the subscriber need only obtain the recommendation of his personal physician. In the hospital, the patient would be subject to regular rules and must make his own arrangements for medical or surgical services, fees for which are not included under the group plan.

Karl Eilers, president of Lenox Hill Hospital, is president of the Associated Hospital Service, which has been chartered by the State Departments of Insurance and Social Welfare. Vice-presidents are Stanley Resor, vice-president of the Manhattan Eye, Ear and Throat Hospital, and Dr. Walter T. Dannreuther, former president of the New York County Medical Society and representative of the co-ordinating council of the five County medical societies in the City.

Oneida County

Dr. C. H. Baldwin was elected president of the Utica Medical Club at the annual meeting. Others elected were: vice-president, Dr. Frederick R. Ford; secretary-treasurer (re-elected for sixth term); Dr. Daniel E. Pugh; trustees, Dr. Clarence Russell, and these re-elections, Dr. R. O. Lees, Dr. John Rossi, Dr. P. L. Turner and Dr. H. H. Shaw. The fortieth annual outing will be held in May.

Onondaga County

Dr. Frank W. Marlow was guest of honor recently at a dinner in the Onondaga Hotel given by colleagues in the eye depart-

ment of Syracuse University College of Medicine in observance of his 50 years of service to the college and the community. Dr. Marlow is professor emeritus of ophthalmology.

Queens County

Plans for six medical courses, arranged by the Committee on Graduate Education of the Queens Medical Society, are announced by Edward C. Veprovsky, committee chairman. The courses are to be given in the various hospitals of the County and are open to general practitioners and specialists. There is a small fee for each course except the one on "Early Diagnosis of Pulmonary Tuberculosis," which is financed by the Queensboro Tuberculosis and Health Association, and will be given free. Dr. Edward McSweeney will direct the course.

Drs. George J. Lawrence, Frederick Carpenter, and Samuel L. Mitchell will give a course in clinical obstetrics at Flushing Hospital.

Drs. Luvia M. Willard and Henry A. Reisman will give a course in pediatrics at Jamaica Hospital, and Drs. James Reuling and James Dobbins will lecture on contagious diseases in children at Queensboro Hospital.

Dr. Irving W. Ponemon will give a course in x-ray diagnosis at Mary Immaculate Hospital, Jamaica, and Dr. Rudolph Boenke will teach the course in skin diseases at St. John's Hospital, Long Island City.

Crowns naturally go to Queens, and this borough appropriately wears the diadem for the lowest death rate of any place in the United States last year: 6.5 per 1,000 of estimated population.

The most threatening rival for the health crown is Detroit, claiming a next-best death rate of 7.3 per 1,000.

Other pretenders to the throne (86 large cities in the U. S.) claim an average rate of 11.4 per 1,000. Long live the Queens!

Tioga County

Dr. I. N. Peterson, of Owego, secretary-treasurer of the Tioga County Medical Society, was elected president of the Tioga County General Hospital staff to succeed Dr. W. A. Moulton, of Candor, at the annual meeting of the staff. Dr. Leon S. Betowski, of Waverly, was re-elected vice-president and Dr. John B. Schamel, of Waverly, was named secretary-treasurer.

The rotating staff for handling County welfare cases, which was started last year by Dr. Moulton, was approved by the members for continuance.

Medicolegal

LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

A Salutory Decision

The Education Law of the State of New York which provides for the regulation of the practice of medicine also contains an article regulating the practice of optometry. This article restricts the practice of optometry to persons holding a certificate of graduation in optometry. Persons now desiring to practice optometry under the provisions of the law must in order to obtain such a certificate complete a high school education and graduate from a school of optometry approved by the Board of Regents, and in addition must successfully pass the State Board examination and must meet certain requirements set up by the Board of Regents as to character and fitness.

The practice of optometry is defined by the Education Law as follows:

A person practices optometry within the meaning of this article who by any means or methods, other than by the use of drugs, diagnoses any optical deficiency or deformity, visual or muscular anomaly of the human eye, or prescribes lenses, prisms, or ocular exercises for the correction or relief of the same, or who holds himself out as being able so to do.

Recently a decision was handed down by one of the Justices of the Supreme Court of this State in a case* in which the question as to whether a corporation may practice optometry was ruled upon.

An application was made to the Secretary of State offering for filing a certificate incorporating a company, in which certificate the following was included among the proposed purposes of incorporation:

To carry on the general business of opticians and dealers in optical goods, lenses and glasses of every description. To manufacture, grind, prepare, buy, sell, import, export, distribute and deal in eye glasses, spectacles, lenses, opera and field glasses, magnifying glasses, mathematical and scientific instruments, cameras, photographic supplies, thermometers, and any and all materials and accessories used in connection with or pertaining to the same or in the manufacture thereof, and appliances, devices, articles, and materials used by oculists, opticians, physicians, surgeons, and scientists. To transact and carry on the optical business; to do, render, and perform *optometrical* and *oculists'* work and services and to engage in the practice of

optometry, provided it employs only licensed optometrists to do the work. To grind, polish, cut, fit, and shape glasses for all purposes.

The Secretary of State rejected the application and returned the proposed certificate of incorporation on the ground that a corporation may not lawfully be organized for the purpose of performing optometrical and oculists' work and services and to engage in the practice of optometry even though it should be specifically provided that the work should be done only by licensed optometrists.

A proceeding was instituted in the Supreme Court for the purpose of obtaining an order of mandamus directing the Secretary of State to accept for filing the proposed certificate of incorporation. The court denied the application and rendered an opinion sustaining the action taken by the Secretary of State.

In the course of the opinion the court noted the fact that while the Education Law contains a definition of the term optometrist, there is no statutory definition of the term oculist or optician. In the absence of such statutory definition the court stated its own definitions as follows:

It would seem that an oculist, whose technically correct title is that of an ophthalmologist, is a physician specializing in the diagnosis and treatment of diseases of the eye. He, as well, examines eyes for the purpose of determining whether glasses are needed, prescribes lenses, when necessary for the correction of vision, and in the practice of his profession, is often called upon to perform surgical operations on the eyes.

An optician is not a licensed practitioner, but is one who makes eye glasses and lenses and fills prescriptions of the oculist or optometrist, much in the same manner as the druggist carries out the direction or prescription of the physician.

The court in determining the application, pointed out the law has been well settled that a corporation may not be organized for the purpose of practicing either law, medicine, or dentistry, and determined that since by statute optometry is given a place with the other professions whereby its practice is regulated for the purpose of protecting the public from unscrupulousness, ignorance, unskillfulness, deception and fraud, the same rule should follow. In its opinion the court stated as follows:

* Matter of Stern, Supreme Court, Albany County, Special Term.

If it is repugnant to the policy of the state to have the profession of medicine, of dentistry and of the law practiced by a corporation, it would seem to be quite as repugnant to have the profession of optometry practiced by a corporation. The rule laid down in *Matter of Co-operative Law Company* (which dealt with the practice of law by a corporation), 198 N. Y. 479, is as applicable to the practice of optometry as to the practice of the law. The practice of optometry may be carried on only by those persons who have complied with the statute and have met the required qualifications as to moral character and educational fitness. It necessarily follows that the right to practice optometry is a personal one and confined to real persons and not to legal entities. A corporation as such cannot meet the requirements of the statute; it cannot have completed a course in a high school or in a university where optometry is taught, nor present the necessary certificate of character. It cannot pass a state board examination or present a degree earned in a university. . . .

As I see it, optometry, like the law, "is not a business open to all, but a personal right, limited to a few persons of good moral character, with special qualifications ascertained and certified after a long course of study both general and professional, and a thorough examination by a state board appointed for the purpose." The relationship between an optometrist and his patient is of a personal and confidential nature, not unlike the relationship between an attorney and client, or physician and patient. The examination of an optometrist may not only indicate an eye condition, but may disclose other ailments and bodily afflictions of a more or less personal nature. True, the optometrist may not lawfully treat his patient for these ailments, but his patient is entitled to the assurance that the knowledge obtained in such examination shall be held inviolate and not become a record in the files of a business corporation. The practice of law by a corporation in this state is prohibited by statute, but quite apart from the statute, it is and was before the enactment of the statute against the public policy of this state.

This is a salutary decision. Once again the courts of this State have put their stamp of disapproval upon attempts by corporations to engage in activities which are against public policy and contrary to the spirit of the statutes of this State, and in conflict with the adjudicated cases of our highest courts.

Dr. Harry Plotz, Brooklyn medical man who when only an interne at Mt. Sinai Hospital discovered the bacillus of typhus, has received a new honor from France, where he has lived and worked for the past 15 years.

Already a Chevalier of the Legion of Honor, he has been promoted to the rank of

Claimed Negligent Diagnosis and Treatment of Fractured Shoulder

A physician was consulted by a patient with reference to a general physical examination for a report to a society which supplied a sick benefit to its members. The doctor examined him and found him in good condition and forwarded his report to the society. A few weeks later the patient returned and stated that he had fallen down a flight of stairs and claimed to have pains in his back and the doctor examined him but could find no injury whatsoever. A few days later he was called to the patient's home and patient was in bed with a compress on his head and still complained of a pain in his shoulder, and the patient pleaded with the doctor to make out a sick certificate in order to receive the benefit from the society.

Finally the patient insisted that the doctor make out a certificate stating that there was a contusion of the shoulder, which was the fact. Doctor was called again about a week later to the patient's home and the patient again wanted a further certificate stating further injuries. This the doctor refused to make out, explaining that he had no injuries whatsoever outside of the contusion, which had cleared up. The patient became angry and discharged the doctor. Doctor heard nothing further for awhile until he found out that patient had gone to a hospital and had been there approximately for a week and had had x-rays taken. The doctor went to the hospital and examined the x-rays and records, which verified the doctor's find, to wit, the patient had suffered no injuries whatsoever.

A few weeks later doctor was served with a summons and complaint alleging among other things that the patient was suffering from a fractured shoulder which the doctor had failed to reduce or cure, and as a result of it he had become so crippled that he was unable to attend to his business. About a year after the suit was started, no steps having been taken by the patient to press the case for trial, a motion was made on behalf of the doctor to dismiss the suit for lack of prosecution. This duly came on in court and the patient's attorneys failed to appear and the case was dismissed.

Officer, according to an announcement at the French Ministry of Foreign Affairs.

Dr. Plotz, who formerly lived at 159 Halsey Street, and who went through Boys High School before going to Columbia, is only 45 now. At 24 years he made his typhus discovery in 1914, and in 1915 he announced discovery of an anti-typhus serum.

Across the Desk

The celebrated "Detroit Plan" of medical care has completed its first year, and the official Detroit *Medical News* reports that "the most important man—the patient—believes in and is satisfied with this set-up," and the "allied professions" of doctors, specialists, dentists, nurses, pharmacists, believe in it, but "the paid sociologist remains critical and dissatisfied." The Bureau handled 1,739 patients during the year, with total fees of \$142,349.50, of which \$45,743.16 has been collected. More is coming in all the time, for under this plan the patient has the doctor of his own choice and the Bureau makes out a plan or budget by which the worker can pay his account out of future earnings. It is heartening to read that "the daily evidence of gratitude from patients served is the stimulus to the Board of Arbitration and the Officers of the Wayne County Medical Society to go ahead with the plan and further the service of the Bureau."

A weary medical editor in the Middle West remarks that "sometimes when we are tired and we listen to papers, the main thought we carry away is that we have heard a vocabulary on parade."

People who think the medical profession is overcrowded may be interested to know that the Maine State Bureau of Health is advertising for doctors to take up country practice. The opportunities "are all for young men who are willing to work and willing to answer night calls. No subsidies are provided," the young M.D.'s are warned, for the reason that "all of the opportunities are good enough without a subsidy."

Talk is heard from time to time that too many hospitals have been built. Well, a nationwide survey made by Alden B. Mills, managing editor of *The Modern Hospital*, reveals that no less than 31,000,000 of our people and 29,000 physicians live in areas seriously deficient in hospital and health services. The States of the South are the ones chiefly lacking proper hospital facilities, according to this survey.

Two swindlers are looking out at the world from behind prison bars in New York City for obtaining \$500 from one premedical student and \$900 from another by promising to secure their admission to medical schools. They were exposed through the activities of Prof. William MacTavish of New York

University. Unfortunately their sentences were only a few months and they will soon be out to resume the "racket."

"Chicle allergy" is brought to our notice by Dr. A. I. Kleinman, of Brooklyn, who reports in the *J.A.M.A.* two cases where sneezing, coughing, and nasal and asthmatic symptoms were traced to chicle, the base of chewing gum.

Two investigators at Antioch College have found that when an expectant mother smokes heavily, the heart of her unborn child beats faster. Whether the child's health is affected unfavorably awaits further study, but the investigators remark that it is "not improbable."

The license of Dr. Clayton E. May, of Minneapolis, who treated the notorious bandit Dillinger while he was in hiding there, has been revoked by the Minnesota State Board of Medical Examiners. This action was taken, not because Dr. May attended Dillinger, who was entitled to medical treatment, but because the doctor conspired to conceal him and provided him with a refuge in order that he might escape arrest. In fact, the doctor was convicted and sentenced to the Leavenworth penitentiary last year on that charge.

The greatest peril to the medical profession today is "bunk" in the opinion of President W. J. Leach of the Indiana State Medical Association. There is the bunk of the "drugless healers, who crack the joints and stretch the imaginations of their victims, following an advance payment of the fee," then the bunk of the faith healers, and third, the bunk of the quack doctors and quack remedies, "an incalculable menace to the public and the medical profession alike." The medical men are to blame for meekly letting these "bunk vendors" mislead the public, says Dr. Leach, and he calls on the doctors to start a vigorous educational campaign of "anti-bunk."

American physicians have seen with a certain sense of wonder the names and pictures of French, German, and Austrian physicians paraded in large advertisements in our newspapers as endorsing various products. The products themselves may be perfectly unobjectionable, but the display of medical names and photographs in circus-

poster style makes our physicians emit a slight gasp. Now it seems that the matter has been taken up by the French Minister of Foreign Affairs and the society that has charge of foreign medical relations, and it is found, according to the *Presse Médicale*, of Paris, that "the photographs and accompanying, endorsements have been published without the consent or knowledge of the respective medical men." Suave interviewers, we are told, extracted statements from the eminent medical men which they twisted into endorsements of their particular foods or drugs. The photographs were bought from picture dealers. French doctors have been warned against this practice and future interviewers are likely to have a chilly reception.

The well-known feat of a plain country doctor named Dafoe is bringing out interesting remarks on what other country doctors have done. A writer in a Kansas medical journal remarks: "And by the way. If you have ever perched yourself on a wooden box with your feet on the cross-bar at the foot of a 'sanitary cot' to keep them out of water on the floor of a leaky shack, with one good lady neighbor holding a kerosene lamp while you repair a perineal laceration, and another neighbor lady holding an umbrella over the newly born heir (or heiress) to keep it at least meteorologically dry while the father nonchalantly pats the head of the family dog that is sleeping on a pile of burlap bags by the stove—we say if you have ever done this, then you have done country obstetrics."

Druggists who nullify the doctor's best efforts and finest skill by substituting inferior ingredients in compounding the prescriptions are getting what is due them. *American Medicine* tells us that one of them in the Bronx was recently given a fine of \$500 or 90 days in the workhouse for this shady trick. The fact that this sort of thing is going on should convince both doctor and patient that it is wise to trust only chemists of character and conscience to put up the medicines on which health and life depend.

The penalty was imposed by presiding Judge Thomas F. McAndrews, and the specific offense was the violation of the retail drug code by substituting another product

upon a prescription calling for Ergoapiol (Smith). The prosecution was conducted under the Shackno Act which makes it a state offense to violate the NRA. Concurring with Presiding Justice McAndrews were Associate Justice John V. Wood and Hyman Rayfiel. The prosecutor was Assistant District Attorney Lawrence Peltin.

Justice Rayfiel before sentence was pronounced severely condemned the practice of drug substitution as follows: "The fact, Counsellor, that he [Klausner] was never convicted before need not necessarily be cited as a certificate of good character. There were a number of complaints made against him before. Now, of course, the court always takes into consideration the man's family and all that. It is really a pitiful thing that people who are served by him also have families, and to substitute drugs in any form is a very dangerous proposition, as you very well understand. You are dealing with human safety and possibly human life. The idea of getting drugs that are stale or inefficient is liable to cause a great deal of harm, even beyond the help of a reputable physician. Those things are essential, very essential, Counsellor." The defense counsel pleaded: "He is not a chemist, if your honor please is not familiar . . ." and was answered by Justice Rayfiel: "I know, but he employed pharmacists with instructions to do what he told them, not to use their own judgment, but to do what he told them. The probation officer informs us there was one man who actually was discharged by him because he refused to do the things that he wanted him to do, is that right?"

Leprosy may be spread by apparently healthy persons, who do not yet show clinical symptoms of the disease, remarks *The Diplomat*, organ of the National Board of Medical Examiners. Evidence that this may be the case has just been reported to the U. S. Public Health Service by one of its officers, Dr. N. E. Wayson, director of the Leprosy Investigation Station at Honolulu.

Persons may be infected with the bacillus of leprosy and remain well for a long time, if not indefinitely, it appears from the studies Doctor Wayson and associates have been making in Hawaii.

THE DOCTOR GETS HIS MAN

Two hold-up men learned a lesson a few weeks ago which they can ponder while behind the bars. One evening in January they summoned Dr. E. C. Lyon, of Bridgeton, New Jersey, by a fake emergency call, and when he came they took his watch,

money, and car. The doctor at once notified the police, who captured the men before noon the next day.

The doctor's property was recovered, and confessions were obtained from the robbers.

Books

REVIEWED

The Laboratory Notebook Method in Teaching Physician Diagnosis and Clinical History Recording. By Logan Clendening, M.D. Octavo of 71 pages. St. Louis, C. V. Mosby Company, 1934. Paper, 50c.

This is a small inexpensive pamphlet which attempts to teach physical diagnosis by applying laboratory instruction methods. The proper method of history taking and physical examination are indicated on one side of the page by well directed questions, while on the opposite page is space for notation of findings.

The method appeals to the reviewer for he feels that it is the proper one to teach accuracy in recording physical findings in a systematic way. In addition, this method will give the instructor an opportunity of knowing whether the student actually saw, felt, and heard what he was expected to.

ARTHUR E. LAMB

The Patient and the Weather. By Wm. F. Petersen, M.D. assisted by Margaret E. Milliken, S.M. Volume III, Mental and Nervous Diseases. Quarto of 375 pages, illustrated, lithoprinted. Ann Arbor, Edwards Brothers, 1934.

Even though one may not accept many of the tenets of the author, one cannot help but admire the scholarly work of Dr. William F. Petersen of the Department of Pathology and Bacteriology of the Medical School of the University of Illinois.

Many of us have always felt that changes in the weather affect our moods; but we have never stopped to question why or how. The author, however, presents a wealth of material and formulates a theory which, he contends, demonstrates the fact "that meteorologically induced alterations of the humoral milieu are associated with changes and behavior of the patient." To substantiate his theory the author presents the case histories of patients suffering from the psychoses and from such diseases as multiple sclerosis, tabes, poliomyelitis, and epidemic meningitis. Numerous charts of weather conditions are submitted to show that psychic alterations in these patients are actually initiated by meteorological events, and that a close relationship exists between reactive states and the weather.

In the case of such diseases as multiple sclerosis, the author contends that meteorological alterations produce vascular spasms which result in anoxemia of the central nervous system; and prolongation and frequent repetition of this state ultimately re-

sults in localized degeneration. Personality types, as delineated by Kretschmer, are a very important factor in the author's theory and he stresses the fact that the various types present chemical differences which are dependent on meteorological events.

Petersen sees in the changing mental picture of the psychoses merely alterations of the chemical state of the body. While it may be an attractive theory the reviewer feels that few psychiatrists will subscribe wholeheartedly to it. Certainly the psychoanalysts will take issue with him when he says, "I have the impression that the vogue of psychoanalysis, too, has been a handicap" in the study of mental diseases. He completely disregards the work of Freud, Abrahams, and others on the psychoses.

On the whole the book is stimulating and opens up a possible new avenue of approach to an understanding of nervous and mental diseases. The third of a series of a study on "The Patient and the Weather," this volume deals with nervous and mental diseases. The cases are from the Psychiatric Institute of the University of Illinois. The author was assisted in his studies by Dr. Low, who made the psychiatric examinations, Dr. Olkon, who studied the skin capillaries, and Dr. Darrow who made the psychogalvanic studies.

The publishers found it necessary to use a different format which they feel is as clear and legible as a printed text. However, the reviewer found it tiring to the eyes. One can appreciate the fact, however, that with the large number of text figures only some such process could keep the cost of publishing at a minimum.

JOSEPH L. ABRAMSON

Gynecology. By Brooke M. Anspach, M.D. Fifth Edition, revised. Octavo of 832 pages, illustrated. Philadelphia, J. B. Lippincott [c.1934]. Cloth, \$9.00.

To review the fifth edition of this well-known textbook on gynecology is an enjoyable task. The statement of the publishers that this edition is re-illustrated, reset, and completely revised by the author is fully borne out by a careful reading of the text. In this day of gynecology and obstetrics in the form of multiple volumes and of monographs we may possibly lose sight of the importance of a well done single textbook.

This book is unusual in several respects. It gives the fundamentals of gynecology

clearly and concisely. It is up to the minute in its consideration of the newer aspects of gynecology. It will be found of value not only to the student and to the busy practitioner, but also to one interested in more extensive study, for each chapter closes with an ample bibliography. Complete revision is attested especially by the chapter on physiology, where the more recent investigations in the field of endocrinology are clearly set forth. There are extensive references to the work of Corner, Frank, Hartman, Novak, and others.

The chapter on Endometriosis portrays clearly the somewhat conflicting theories of R. Meyer and Sampson. Presacral sympathectomy is skillfully illustrated and discussed in the chapter on Disorders of Menstruation. Several chapters are devoted to urological gynecology, and there is one on sterilization and therapeutic abortion including a consideration of methods of contraception.

The illustrations throughout the text are on the whole excellent, especially in the case of the generous sections on operative technic. The work is perhaps fittingly concluded by a splendid chapter on Radiation Therapy.

The reviewer believes this text to be an excellent single volume presentation of gynecology for students, and since it is as up-to-date on new and controversial subjects as it is possible to make a textbook, it can hardly be beaten as a ready reference for the busy practitioner. Even the specialist may find it of value as an up-to-date text for its unusually complete bibliography.

The author and the publishers are to be congratulated upon the new fifth edition of this already well-established work.

ONSLow A. GORDON, JR.

Cataract. Its Etiology and Treatment. By Clyde A. Clapp, M.D. Octavo of 254 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$4.00.

Here is a fine volume which brings together in a clear course manner the recent progress of our knowledge of Cataract. Particularly valuable are the chapters on "Embryology," "Slit-lamp Anatomy," "The Metabolism and Chemistry of the Lens," and the short, snappy descriptions of the numerous forms of operative technic.

Needless to say, the various types of cataract are elucidated, and though the reviewer does not feel that a classification of characteristics is particularly facilitated by this work, yet it is a direct step toward the time when a completely satisfactory classification will be possible.

It seems to the reviewer that this work supplies a definite need in modern ophthalmic literature. Dr. Clapp in his prefatory note emphasizes the fact that it is not possible to cover the entire compass of our knowledge on cataract in this work; nevertheless the reviewer thinks more emphasis might have been placed on one or two points. There is no illustration of the normal lens, nor is there one showing its relations. One is led to expect some sort of picture of these because the section on embryology is so satisfactorily illustrated.

In the chapters on operative technic, a beginner would have difficulty in understanding the mechanism of lens expression, the rationale of the procedure; illustrations showing the lines of force directing the unseating of the lens, and so on, would, to the reviewer's mind, make for more lucidity.

Under the heading of "Preparation of the Patient" we find listed the various types of routine examinations necessary; but Dr. Clapp apparently lays little importance to a study of the gastrointestinal tract—other than the gallbladder—or the genitourinary tract. This is a bit surprising if one believes the modern dictum, "30 per cent of all men over 30 years of age have some sort of upsets of the prostate gland."

In the section on postoperative complications there is a well arranged review of the various problems which may develop; the treatment is outlined for each. There seems to be no discussion of late iritis endogenous unless the author means to accept its occurrence only as sympathetic ophthalmia or endophthalmitis phacoanaphylactica.

Well printed and clearly illustrated it is a volume very worth while.

JOHN N. EVANS
